You could try 4nec2 at www.wyger.nl/usr/4nec2. If you are familiar with
EZnec, you should not have too much difficulties using 4nec2. However
both programs have their pros and contras

Success,
Arie.

The logical resonse to a demand for including refraction in a
purely conceptual lossless laser reflection example is:

"Somebody Get The Net!!!"

So, when judging yourself to that same standard, this is your
response? Yes, Ian did miss an opportunity to call out the net for
you.

I don't think that opportunity will be missed again. No one expects
you to correct your errors, that would be rational.

From the remarks I see on this forum and others, there appears to be a
number of people who only consider how an antenna works for DX. There
are many of us who don't just chase DX. I hunt counties and need
antennas that will cover much smaller skip than someone trying to
operate with russia from here. On late night nets, I need signals
that drown out the 40 meter sw stations and so I can hear my regional
QSOs. Other times, I would love to be able to pick out that rare DX
in the midst of a pileup of multi-kw amps and beams that have more
acreage than the average home.

If someone needs 10-20 deg TOA for a signal, then they need to know
how to maximize their antenna for that angle, that is true. I want to
know the characteristics of the antennas to know how they will work
for various purposes.

No shield needed:)

I'm another Ham that could care less about DX! I just want to use the proper frequency depending on the time of day/night to communicate with some friends located around the west coast. Very few DX stations will hold a rag chew, just slam bam, thank you mam, i.e. 599 OM !... ugh..

At any rate, if I knew more about my antennas characteristics I might could figure out the band/end location where it would be loudest at any given time. Is this all wet, and TOA wouldn't help in that at all?

The problem with the spectral width, and stability, of the magnetron limits is usefulness for low signals. As mentioned before, see http://www-personal.engin.umich.edu/~mcjz/papers/neculaes_tps04.pdf

Now I know what you are doing you might consider a "COHO/STALO" system, as used in MTI RADARs, see http://www.alphalpha.org/radar/coho_e.html With COHO/STALO, you could probably reduce the BW to near 1 Hz with digital filtering.

You may also consider applying the free-space RADAR equation, to determine the feasibility. With a nominal ERP of 4 MW you may be successful without using COHO/STALO. Try pulsing the magnetron with a very low PRF, and use an "A" scan monitor.

Regards,

Frank

The TOA will help in any QSO. A low TOA will tend to open you up to
DX QRM such as on 40 meters, but an NVIS with near vertical TOA will
manage more regional communications than DX. You might not even be
bothered by the 500kw SW station in Germany. Of course, the station
you talk to will also have to deal with that station.

Knowing the TOA is as beneficial as knowing where the nuls are on your
beam.

Agreed, and it's not too surprising. The FCC doesn't regulate
microwave oven leakage, and the FDA's standard limits leakage for an
installed microwave oven to 5 milliwatts per cm^2 at a distance of 5
cm from the surface. I've read that a fairly high percentage of older
microwave ovens leak more than the standard would allow.

That level could add up pretty quickly... a watt or more of leakage
from an older microwave oven would not surprise me very much. A
15-milliwatt Part 15 device can't compete.

>Danny, K6MHE

I said I was done with this subject, But ..... I can't take it
anymore.
Again, the Arrow Antenna OSJ Antenna does NOT need a choke balun.
By that I mean it will make no noticeable difference in performance of
this particular antenna.
(I am not lumping all VHF & UHF antennas together. I am ONLY talking
about the OSJ).
If you don't have a physical Arrow Antenna OSJ to test with and without
a balun, you don't know what you are talking about.
That goes for computer modeling also. You can't hook up a radio to
computer model.
This antenna works just fine the way it is.

By the way Danny, what is the name of your Antenna Company ?

No, I don't think it's a useless idea, just one that hadn't occurred to me. It will indeed tell you where your signal will be strong, assuming that propagation is supported in that azimuth direction and at that elevation angle.

The TOA isn't the way to get that information. What you need to do is, first, find out what elevation angle will be used for communication on each band at the time(s) of day of interest. Again, something like W6ELProp is good for doing that. Second, since you're interested in having the strongest signal, look at the signal strength reported by W6ELProp or other propagation program at each of those times. Next, use EZNEC to look at the gain of your antenna at the elevation angles you found with the propagation program. Finally, add the antenna gain to the signal strength reported by the propagation program at each band and time. The largest number will give you the best signal. This of course comes with the caution that propagation prediction is generally much less accurate than antenna pattern calculation, so there can be a lot of variability in the accuracy of the results.

I think that if you go through this exercise a few times, you won't find much correlation between your results and the TOA.

That's a good and perfectly valid point. Knowing the TOA would be useful in determining what range of distances you're most likely to encounter QRM from.

Thanks, Greg.

I've printed out their catalog and noted the products you suggested.

Yesterday afternoon I had an opportunity to examine our busses more closely and found a couple different types of antennas in use. Several look very much like the ASPRD1610 shown in the catalog. The others look like the ASP-7654, but perhaps with a different base. I have always understood that when it comes to antennas, the longer they are the better(in general). The short ones appear to be between 4-6 inches in length. There is some variation in their lengths. Given their varied mounting locations on the busses combined with what I learned yesterday about how things have been done here, I can only assume that very little is actually "right". At this point, I'm not very confident that

the local supplier pre-cut the antennas, although they may well have. A phone call will answer that.

As an aside, this particular company appears to make little if any investment in their people. The manager here must get prior approval from the regional manager to purchase string for the weed-eater. This may well help explain why there has been no service contract in place, nor has there been any attempt to fix the problem(s) with the radios. This makes me think that other than our remounting the antennas properly and cleaning connections there may be little we can do. Perhaps that will be enough to get our communications to a point of being adequate for our needs.

Anyway, thanks for the information. I'll let you know what we find.

Mike

Allen,

My comments were directed to Ed not you, however, can you please explain to me what is the magical ingredient in your OSJ that makes it different than any other antenna known to man in that there will be no common mode current on a coax transmission line when directly connected to the antenna?

Understand I am not saying your antenna doesn't work - never did say that. I will say that using a choke at the antenna's feed point will assure that the antenna will be operating at its best (maximum signal towards the horizon). By not using a choke can cause an increase to high angle radiation at the cost of reducing radiation toward the horizon due to common mode current on the transmission line - just like any other VHF antenna feed with coax. In other words the antenna is still radiating the same amount of power, however, much of the your signal is being wasted in the wrong direction (unless you are talking to airplanes). For the sake of me I can't fathom why you can not understand that.

As for you question: I did not claim to own an antenna company. Is that germane to the subject of the thread?

Of course, he could just check to see which antenna hears the station
the best with the least QRM.

From what I understand, the TOA of a DX station changes over time. It
may come in at a low angle and then rise a bit or visa versa. Or it
may never get high enough for a particular antenna

Frank,

Thanks for the advise.

Obviously if it was trivial to modify magnetrons for communications in the 13 cm S band, there would be a lot of high power activity on that band and fewer dead microwave ovens in landfill sites.

Surely a near KW of radio energy can be used for more than re-warming left-overs. Maybe not.

Hi Adrian,

Only when your antenna's adjustment is more than your arm's length
from the transmitter during tune-up. It looked like your antenna was
outside, and your transmitter inside. When you transmit, what do you
do to adjust SWR?

Have you tried applying power to the antenna?

Hi Mike,

You can expect some "minor" variations. Tuning these up will NOT
change a poor situation.

>I'm not very confident that
>the local supplier pre-cut the antennas, although they may well have. A
>phone call will answer that.

The call to the supplier will draw a blank here. They provide goods,
not services. The antennas are "factory tuned." Installation is not
a matter of making things fit like a cabinet maker.

An installer would make sure of sufficient sheet metal to offer the
antenna a counterpoise - this is an implied presumption that a garage
mechanic would be wholly unaware of. In this regard, your antennas
WOULD be seriously detuned. Trimming them will do absolutely nothing
to improve this. As has been pointed out, you need real metal
footings.

Researching this last point may take some effort to match to your
situation of neglect and tight purse strings.

>As an aside, this particular company appears to make little if any
>investment in their people.

You run in serious chance of upsetting the apple cart in an attempt to
shine - not the response you would care for. A friend once pointed
out to me in a similar situation:
If it was important to them, it wouldn't be a problem.

>connected to the antenna?

May I chime in? Here's my best guess as to the situation with this antenna:

- Like any other VHF antenna without an effective feedline- decoupling arrangement and isolation from the mast, it's possible for the feedline and/or mast to carry some amount of RF current. Quite simply, there's nothing stopping this from happening.

- The RF impedance of the feedline shield and/or the mast will appear in parallel with the impedance of the longest (2-meter radiator) and shortest (440 matching arm) elements on the OSJ.

- What this impedance will be, will be extremely installation-specific, and so will the currents carried on the feedline braid and/or mast.

- If the length of these elements to the nearest ground is an odd multiple of a quarter-wavelength, the low-Z ground will transform back to a high-Z at the feedpoint, and little unwanted current will flow. If it's an even number of quarter-wavelengths, the impedance on the unwanted element will be quite a bit lower - the lower limit is probably the radiation resistance of a wire of that length. If it's a nonintegral multiple of a quarter wavelength, the impedance will be intermediate between these points and will be rather reactive.

- If the mast is ungrounded at the bottom, the relationships in the previous paragraph will be reversed - high-Z for even number of quarter wavelengths, lower (set by radiation resistance) at an odd number of quarter-wavelengths, reactive in between.

- Since the feedline and mast are likely to be longer than a metre, any radiation from them is likely to be have strong high-elevation-angle lobes. Power radiated in these lobes will be less "useful" in many applications, and since it takes away from the towards-the-horizon pattern of a theoretically-perfect halfwave radiator it

will reduce the antenna's useful pattern gain by some amount.

So far, I think this is all pretty standard per theory.

Here's where I go out on a limb of speculation:

- In a typical OSJ installation, the feedline and mast are relatively long, compared to the near-half-wavelength size of the radiator.

- For this reason, if the feedline/mast length happens to be one with a low and non-reactive RF impedance, its impedance will be a good deal higher than that of the antenna itself due to the higher radiation resistance (e.g. 100-200 ohms). Only a relatively small fraction of the power at the feedpoint will flow into the braid or mast. As a result, the amount of power "robbed" from the primary radiator will be small, the high-angle lobes will be weak, and the reduction in the strength of the towards-the-horizon primary lobe will be minor.

- If the feedline and/or mast happens to be of a length which results in a high impedance appearing at the feedpoint, then even less power will flow on these unwanted elements and the pattern disruption will be even less.

If the above model and speculation are correct, then two things can probably be said:

[1] In many installations - perhaps most - the OSJ probably works just fine without any sort of choking or decoupling arrangement (where I define "just fine" as "Adding a theoretically-perfect decoupling arrangement would not result in an improvement in pattern, ERP, receive sensitivity, etc. which the antenna's owner would notice or consider worth the trouble."

[2] In some installations, under specific conditions (e.g. short 1/2-wavelength-long feedline) a choke might result in at least some useful (or at least measureable) improvement in towards-the-horizon pattern.

I'll finish up by adding a personal observation. As Ed mentioned, the Arrow OSJ (and/or equivalent antennas made by a local amateur) are quite popular among members of our city's ARES group. I've measured a couple of them using an MFJ analyzer, and in my measurements I have *not* noticed the SWR / measured-impedance to change significantly when I touch or move the antenna feedline (even when it's a relatively short 6' piece of RJ58). This suggests to me that (in this case at least) there's not a lot of RF coming back down the outside of the feedline to the analyzer case, and that the near-50-ohm impedance presented by the radiator and matching stubs is the dominant "sink" for the RF current flow.

Do I think the OSJ is perfect? No - no practical antenna is. If I were putting one up for a permanent installation, I'd probably

insulate it from the mast, and loop the feedline coax into a choke balun and/or add a couple of ferrite beads, just because I'm picky and because the effort to do so is so small.

I would not, however, count on noticing any practical difference in performance from doing so, and I wouldn't bother doing this in any sort of temporary or field installation (which is the purpose for which I keep a break-apart OSJ in my van).

To that extent, I think that Al's statement that the OSJ doesn't need a choke, is a reasonably fair one. It's not a universal TRVTH but it's probably a fair, practical rule-of-thumb.

As I recall it is a commercial name for a center insulator for the
common dipole. It was narrow at the bottom to accept the feed line,
and flared out at the top for connection to the dipole elements. With
the transmission line connected it sorta looked like the head of a
cobra snake. I haven't seen a cobra in person, nor have I saw a cobra
head insulator. I think I would like to keep it that way.

Back in the good-ole-days, a cobra head was a triangle shaped device
that had an SO-239 on one corner and connections for the wires of a
dipole on the other two corners. One went to the center conductor and
the other went to the shield side. Then Baluns became popular and now
instead of cobra heads, most people have baluns. However, at that
time in ham radio, "Cobra head" was a generic term that meant the
piece to connect the wires of a dipole to a piece of coax.

An example of an approach to antenna design that starts with identification of the paths to be optimised is at http://www.vk1od.net/7MDipole/7MDipole.htm .

In this case, I was interested in local contacts and over 50% of Australia's population was located in just four cities at distances up to 1000Km. The propagation paths to those locations was modeled to provide the geometry for assessment of antennas in EzNEC.

BTW, 5 to 10 degrees elevation is probably below most propagation paths for DX, let alone local contacts. Lowest angle doesn't necessarily translate to optimal for distant stations (it depends on the propagation mechanism at the time), and the most desirable DX might not be at the greatest distance. Best performance at low angles might assure maximum pickup of local noise sources, and in my case QRM because I am not at all interested in DX.

No the antenna is NOT perfect. Adding a choke would not make it
perfect.
If it was perfect like you want, I might not be able to make contact
with
cross band repeater on a balloon at 60,000 feet 200 miles away. And
still use a repeater 100 miles away, full quieting with 5 watts.
Check the distance between Denver CO & Cheyenne WY.

Your saying all antennas are the same is like saying all antennas with
a gamma match have a skewed pattern.

Here is an excellent and practical discussion of rough design and
practical use of can antennas, make sure to follow the link on the
bottom of the page...

No problem, glad to help. It still might be interesting to plug in the parameters to the free space radar equation, considering receiver noise figure, and signal BW, etc.. I am sure there is data available on the reflectivity of the Lunar surface. Of course COHO/STALO will only work if you are receiving your own signal, so not much use if you are attempting to work others.

As I suspected, some work has been done on the injection locking of magnetrons; as in
http://www.lancs.ac.uk/cockcroft-institute/public/workshop-jul04/tahir.pdf
This presentation recommends an injection signal of 2% power, or 20 W in the case of a 1 kW magnetron. I have no experience on solid state amplifiers at such a frequency (except for TWTs), but the construction of a single loop synthesizer using ,a National Semiconductor chip, and a Z-Communications (or Mini-Circuits etc.) SMT oscillator is trivial. There are lots of eval. boards available for a nominal cost. I think Z-comm. has one, but have not priced it recently. I guess such projects are a bit impractical unless you have a good spectrum analyzer

Using #10 wire instead of 1/8 tubing will very slightly raise the
frequiency, not enough to worry about. If you mount it for vertical
polarization, at least the top 2 feet of the mast should be non metallic,
wood or plastic water pipe. How are you going to match the feedline to the
driven element? I hope the 4 element beam has instructions for that.

Source record: 74809

That's an excellent summary by Dave. However, I didn't see any mention of common mode current due to mutual coupling between the feedline and the antenna. Even if you perfectly choke the common mode current at the feedpoint, considerable current can be induced onto the feedline. This won't happen with a symmetrical dipole if the feedline is oriented at right angles to the antenna. but where the antenna and feedline are collinear, as they are in a J-Pole or ground plane antenna, coupling can be substantial. The criterion for maximum current in that case is whether the decoupled section of the feedline is approximately resonant. For example, a quarter wave feedline grounded at the bottom and decoupled at the top (i.e., with a current balun - common mode choke - at the feedpoint) can have considerable current induced.

It turns out that the conditions for maximum induced current can be opposite those for conducted current. For example, a half wavelength feedline that's not grounded at the bottom end won't have a great deal of conducted current. However, it can have quite a bit of induced current *if decoupled at the feedpoint*. If there's a good balun at the feedpoint, the isolated feedline becomes approximately self-resonant.

Here's an example, for those who have EZNEC:
Begin with example model VHFGP.EZ. First, in the main window, select Units, change to any units other than Wavelengths, and click Ok. Then select Units again, change back to Wavelengths, and click Ok. (This is necessary because of an EZNEC bug I discovered while preparing this. It affects only old files with Wavelength units, which include example files VHFGP and W8JK. When opened, these files will show the wire diameter units as being in Inches in the Units selection, but Wavelengths in the Wires Window. This bug will be fixed in the next update release, v. 4.0.17. In the meantime, you can re-save the files after changing the units and changing back, and they'll be ok from then on.)

Add a wire with End 1 at 0, 0, 5 and End 2 at 0, 0, 4.5, 10 segments. Make the diameter 0.25 inch. This represents the outside of a feedline. Click the Currents button at the left of the main window and look at the current on the new wire, Wire 6. You should see that it's about 0.19 amp at End 1 (the top). (You'll see a different value if you've set a power level in the Options menu.) Now add a decent balun by adding a load with R = 1000 ohms to End 1 of Wire 6 (0% of the way from End 1). Click Currents again. Note that the current is now maximum at the middle of Wire 6, and it's more than twice what it was before -- about 0.42 amp.

This is a situation that I'd frankly never considered before -- where a feedpoint balun can actually *increase* the common mode current! The

current can, of course, be lowered to a small value by adding a second current balun (common mode choke) about a quarter wavelength down the wire (Wire 6, 50% from End 1).

To stop the conducted current, you need a choke at the feedpoint or, alternatively, an even number of half wavelengths from it. To stop the induced current, you need a break up a resonant line by adding a choke about a quarter wavelength or an odd number of quarter wavelengths from an open end, or an even number of half wavelengths from a grounded end. Of course, you can alter the feedline length in such a way that both are minimized without needing a choke.

To coin a phrase: "Fascinating!" Thanks for pointing this out, Roy.

This gives an interesting twist to some advice I'd read several
times... that to choke off feedline current one should install two
chokes or ferrite beads, a quarter of a wavelength apart on the feedline.

I had always assumed that this was simply a quickie way of making sure
that a useful amount of choking reactance was sure to be installed
fairly close to a current maximum, where it'd be most effective, and
that if you knew where the current maximum actually was and put a
choke there, you wouldn't really need to install the second choke.

The fact that the conduction and induction currents behave differently
would seem to rule that out - there really _is_ a good reason to have
two chokes, to handle the two modes.

Hmmm... slightly crazed idea... I wonder if there's a market for a
coax with some amount of ferrite dust mixed into the PVC jacket when
it's extruded, so as to create a self-choking distributed-inductance
feedline. If the more rabid audiophiles can be convinced to spend
thousands of dollars for a one-meter RCA-plug-tipped interconnection,
maybe the excessively- well-to-do ham (there must be at least one)
would pay ridiculous sums for a self-baluning RG-8?

Might be a neat income opportunity, if one could sell it at high
prices and still stand to look at ones face in the mirror the next
morning (I couldn't, but I imagine there are people who could).

Here is what I ended up building:

http://users.adelphia.net/~ryanmeg/8lq.jpg

The one designed for 446mhz

I used a 3/4 by 1.5 inch beam and 1/8th inch brass welding rod with #12 copper THHN wire for the director and reflector.
Works great even with the 8 foot 75 ohm feedline directly wired

Anybody have any ideas on how to improve?

Here is a photo http://users.adelphia.net/~ryanmeg/images/100_0532.jpg

1352. Adding 6 meters to 20

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-17 03:30:02 UTC
From: Buck <iam@this.site>
Message-ID: <lc74b1pnrmgj2caujco5l3slv8kbnkhrqv@4ax.com>
Source record: 74817

I had a 20 meter dipole about 65 feet over the house. The antenna had a flat swr on 14.336 where I often hang out. On the low end, it was too high to use below 14.020 so I only lost use of a portion of the extra portion without a tuner. (flat defined as according to the 706 MKII internal meter.)

This evening I cut a pair of wires 4.5 feet long each. I added them to the 20 meter connection center connection at the coax and let them hang about 8 inches below the 20 meter wire. I also changed coax from cable-tv coax to RG-8 foam. I rearanged the antenna just a little with also allowed for an additional 10 feet of height. I now have a 20/6 meter dipole at about 75 feet high with the legs pointed almost exactly east and west.. 20 meters is now flat at 14.030 and the top edge of the band is only 1.3:1. The 6 meter dipole turned out to be flat on 50.1.

So far, I am quite happy with the antenna. I am having a 6 meter QSO as I write this. (The other party loves to talk and hasn't unkeyed for at least 5 full minutes.)

Based on our current conversation, It appears that my next antenna will be a loop.

Comments are welcome,

Thank you,

Recent editions of the ARRL Antenna Book cover this topic very thoroughly. They note that arrival angles from a given location vary with time of day, time of year, time in the sunspot cycle, whether the ionosphere is stable or disturbed, and so on...

Then they produce statistics for major paths (eg "G-VK"), averaged over all these factors. OK, so these figues are "only computed"... but they are computed using VOACAP (the Voice of America's propagation program that has has years of development and a lot of verification) so this is the best information we're ever likely to get.

The big lesson is that there is ALWAYS A SPREAD OF POSSIBLE ANGLES.

As Owen says, 5-10deg is not always the most likely angle. It all depends on how many F2/F1/E hops will fit into the required path length. That means the arrival angles tend to jump, especially as the band is coming on or going out. (However, it turns out that a substantial fraction of signals on the G-VK path come in at angles of only a degree or two. These paths are workable, of course, but the antennas at both ends will usually have very little gain unless the land slopes down to lower the reflection angle.)

Hams became fixated on "5 to 10 degrees" a very long time ago, and we still tend to wave this figure around like some kind of flash-card. Professionals have moved on to a much better understanding of the range of possible angles that they need, and this is now starting to filter into ham radio too.

If anyone is interested in this subject and hasn't read a recent edition of the ARRL Antenna Book, it's time for an update.

1357. Re: Magnetic loop antenna (again)

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-17 08:25:40 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <d8u1e4$8dg$1@nwrdmz01.dmz.ncs.ea.ibs-infra.bt.com>
Source record: 74822

At the high frequencies you are listening to you can't expect to hear
much noise.

Complain only when you don't hear any signals.

To hear any signals both the receiver and antenna must be tuned
exactly to the same frequency.

How do you ensure that both are tuned to the same frequency?

By the way, the 1/5th diameter coupling loop is much more likely to be
working correctly than the ferrite ring method. There's no way for the
coupling loop to go wrong. It is more efficient too.

There's no need at all for the coupling loop to be made of coax. Just
a length of self-supporting wire is perfectly adequate. Best if there
is no direct connection to the main loop.

Reg, G4FGQ

Hi Dan,

My, you are a bit on the arrogant and foul-mouthed side, aren't you!

It would be tedious to try and dissect your attributions of positions
that I did not take, so I'll skip that.

I'll just point out that as an E.E. with three degrees from a top-5
engineering school, and a lifelong specialization in RF engineering,
I don't need any patronizing lectures from you. "Physician," heal
thyself... or at least try to understand the difference between
theoretical niceties and practical effects. Reading Dave's posts
might help. (He's much more patient with twits than I am, and
explains things well.)

BTW, I have nothing against coax "baluns," unless they become
physically awkward, or noticeably increase cable loss.

Ed

I thought I was too but I can't take it anymore either.

>Again, the Arrow Antenna OSJ Antenna does NOT need a choke balun.

No antenna *needs* a balun. Most will deliver more predictable
performance when they incorporate one however. Your's is not an
exception, in fact, it's a glaring example of where one *should be*
used. Furthermore, a non-conductive support should be used as well.
A balun on a piece of coax that is in parallel with a conductive mast
is worthless.

If these things aren't used, then you are selling only part of the
antenna system; the upper part...with the user is supplying the lower
part. I suppose you could argue that the part you sell, when mounted
directly on an infinite ground plane, doesn't need a balun, but I
don't see that limitation spelled out in your literature.

>By that I mean it will make no noticeable difference in performance of
>this particular antenna.
>(I am not lumping all VHF & UHF antennas together. I am ONLY talking
>about the OSJ).

When "performance" is measured by whether or not you can break the
squelch of the local repeater, then you are correct, it makes no
difference as long as the squelch is broken.

>If you don't have a physical Arrow Antenna OSJ to test with and without
>a balun, you don't know what you are talking about.
>That goes for computer modeling also. You can't hook up a radio to
>computer model.

Uh huh. So since you don't trust modeling, I guess you have a high
class antenna range that you use to design your antennas. That must be
how you substantiate such claims as, "This antenna has a good
combination of gain, front/back & bandwidth" and where you prove that
the pattern of your J-pole is unaffected by the supporting mast and/or
transmission line.

Whoops---wait a minute---right here:

http://arrowantennas.com/inst/ijpole.html

I see 3D radiation plots made from a *COMPUTER MODEL*.

Plus I see SWR plots that (convienently) are 1.0:1 over the whole 2-meter band. That is amazing. My dummy load isn't that good.

Look. I'm sure you're a very nice guy and we would probably enjoy having a few beers together. I've already commented on your ingenuity in designing and constructing your production machinery and your products seem to be very well made.

But your performance claims are over the top and while I know that almost everybody in the ham antenna business is prone to rub a little snake oil on their ads, it doesn't mean that I'm going to agree with it or refrain from skewering those who do it.

Hello, Danny, K6MHE

I am not missing the point, I just have a different point I have to
deal with.
Check the last few posts, especially the one from Roy.
Can you imagine trying to explain that to some one that don't
understand why
the coax he took off an old computer network don't work with his 2
meter radio.
You have to realize, a lot of times I am dealing with hams that just
got their
license last week. One's that have trouble putting a connector on
coax.
A lot of the time they don't even have an SWR meter, or they are trying
to use one from their old CB.
The ham buying a $39. antenna that don't have to be tuned or adjusted,
is
at a different knowledge level than a ham that can set up an EME
station.
I am not an antenna guru, I know less about coax & baluns than I know.
That's why I have been reading this newsgroup for the last 10 years.
Why heck, I cant even spel.
The OSJ is a good entry level to antennas. It get's them on the air,
so
they can learn more.
I think I am doing a good service. At least I feel good reading the
e-mails I get almost every day from people using my antennas.

Al, I have a fair idea of antennas and baluns and how the electrons and homotrons bounce around these magical devices..

Your antenna works well for it's intended purpose. I have two of your J-poles, one on the house and one on the roof of the car. (Takes 6 large rubber bands to remove the mechanical resonance at 70 MPH) They connect me with the local repeaters, withstand hurricane winds, and are trouble free. At $39.00 a bargain by any description.

Many here enjoy picking fly crap out of pepper, that is their enjoyment of ham radio. No different than
contester, DX hounds etc. I enjoy the discussions of folks that will spend days bloviating on the state of an electron named George at an SWR of 1.000000001:1.

These folks have caused me to think, as well as learn, just to keep up with the pin dancing. That's a good thing

While some can appear officious and supercillious in the process, once you get beyond that, pearls of wisdom do appear.

Continue making a great antenna, those that desire to achieve antenna nirvana may spend time with the tweezers removing the afore mentioned flyspecks.

I will be in Ontario and Los Angeles, CA area this weekend and will have a lot of free time. Are there any good electronics/Ham stores in that you would recommend? Electronic Surplus stores that have radio gear/parts are a plus as well.

I have an internet connection at my hotel, so any responses anytime this weekend will be read.

Thanks!

1369. Different style resonant antenna - 3:1 bandwidth

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-17 17:15:51 UTC
From: Bill Ogden <wogden@attglobal.net>
Message-ID: <xvDse.32$ik5.1@fe12.lga>
Source record: 74734

One ARRL stand (at Dayton) handed out small, black foam balls that are intended to be stuck on the end of a whip antenna. Stops corona (maybe -- let us skip that discussion).

I do not normally have a transmitter in my truck, so I stuck the ball on my standard truck radio antenna. (It is a 2003 Ford Ranger.) Since doing this I have noticed that the antenna almost always vibrates a little -- even after sitting stopped (engine off) in the garage for many minutes. The ball on the top moves at least 1/8 inch; it is easily seen if I focus on it.

It appears I have a good resonant antenna to sustain this motion for long periods, across an almost 3:1 range (the AM broadcast band) and a bonus VHF range (the FM broadcast band). I assume that Hooke's law (if I remembered the right name for it) applies instead of the break-from-metal-fatigue-or-metal-work-hardening-law will apply such that the antenna does not snap off sometime. Perhaps I should patent this resonant antenna that is almost frequency independent!

Bill

| > Our local cable company, Comcast, doesn't carry FM radio signals;
| > therefore, I'm trying to improve my FM reception on my home receiver.

One of the antennas I use with some success is what I call my "picture frame" antenna, as it's mounted on a picture frame with the standard dimensions of about 3 by 4 feet (with a "painting" by a Starving Artist or whatever) which gives you a circumference of about 14 feet, or about the wavelength of an FM signal. Buy sufficient *unsheilded* twin-lead from your local electronics supply store, cutting a length sufficient to mount it around the frame, using nails, glue or whatever works to keep it wrapped around the frame.

Taking the excess (you DID buy excess, didn't you?) attach one wire to one of the wires of this loop. Follow the loop around the frame, to assure then that you have the other end of this wire at the other end of the loop. Connect *it* to the remaining wire on the side already connected to your feeder, and then connect the last wire to the free wire on your feeder. The end result is you'll have two loops, at about the correct wavelength for FM. Hams and CB'ers use a similar design, called a cubical quad, which you might see on towers...they're squares, mounted some distance apart, and are very directional.

This antenna is somewhat directional as well. If you have problems with some local strong stations, it might be possible to reduce their strength if your antenna is properly oriented. You can hang the picture directly over your receiver (assuming you don't mind showing an Elvis on velvet) or simply place it behind your stereo cabinet if you have one. Using this antenna I've pulled in stations from over 120 miles away consistently with a good line of sight (Erie PA to Toronto, where most of the FMs were at lower than normal power, high atop the CN Tower), on a receiver not particularly sensitive. Your results may vary.

Hi Fred,

I've seen you use this platitude more than once. As much truth as it
may offer, it necessarily presumes there is someone energetically
putting fly crap into the pepper.

I won't tarry to imagine how that is done, however.

Greg,

I have no delusions about a long-term relationship here, and certainly not in terms of my being able to effect meaningful change. Rather, my concern is strictly a safety issue. There have already been several minor incidents involving unruly students where a driver may radio in and we have had difficulty receiving/understanding the message. On another occasion a driver stumbled upon a crime in progress at the end of a very rural road. Our driver used her bus to block in a bus driver from another company/district until the police arrived nearly an hour later. Adquate communications is vital under such circumstances.

I refuse to attempt to "manage from the bottom" as the results are unprofitable, counter-productive, and nearly always fatal. I may have taken this as a stop-gap until something else came along, but I do believe that this is an issue worth researching in the hope of making a small but important difference.

PS: Are you hiring? ;)

Mike

Source record: 74740

Found the following interesting site: http://www.df9cy.de/pathloss.htm
There is a downloadable spread sheet concerning moon-bounce path loss. I
have not verified the accuracy of the spread sheet, but it looks reasonable:

From the spread sheet, if you plug in the following parameters:

Power 1 kW;
BW 3 MHz;
Antenna gain 35 dB;
Frequency 2.4 GHz
and many more, such as noise figure, etc.

The received signal will be 40 dB below the noise.

Reducing the bandwidth to 100 Hz the signal will be about 4 dB above the
noise
-- as 10*log(BW1/BW2) will confirm.

Reduction in bandwidth to between 1 and 10 Hz would seem to be desirable.
Stability required is about 0.0004 ppm, not to mention degradation due to
TCXO 1/f noise.

Ken,

About the best place to start would be L.B. Cebik's web site
http://www.cebik.com/radio.html

Also the help manual which is included with EZNEC has excellent
information.

And if you are not opposed to spending some money the ARRL offers a
course on antenna modeling. I believe it is possible to purchase the
course text book without taking the course. That book was written by
LB also.

It is always present Richard, but only the most anal take the time to pick it out.

The similarity in appearence requires a very exacting inspection.

This is best carried out by the same people who would worry about the last .01 dB of gain, removing the last milliwatt of coax radiation, and other esoteric stuff that means as much as the fly crap.

The tenna-topper used to be Orange styrofoam - free with a fillup at the
"Union-76" station on the corner. (late 60's)
I don't think it stops corona or helps or harms the antenna in any way -
unless by making it easier to blow down.
One interesting experiment to try is put a ohmmeter on it - and - If
infinity, then maybe borrow a megger.

That's a good example of the ham spirit of experimentation.
A different antenna design might start with someone saying "I wonder how it would work if I made this change."..
I tried a different style once - multiple home-made coils on a long antenna - I need to revisit that experiment now that I have the MFJ Antenna Analyzer.

Based on our current conversation, It appears that my next antenna
will be a loop.

Comments are welcome,

Ok...Live a little...Build a yagi for 6m...Will smoke the
dipoles and loops, etc...I built a 3 el NBS yagi all from
hard drawn copper tubing. I think it cost about $20 or
so for the tubing...I built it all one piece using a torch to
weld the elements to the copper boom. The elements
are 1/2 inch. The boom , 1 inch I think...
Actually on 6m, anything is probably ok...But my 706
does not like big wire antennas. Brings in too much
HF signals, and trashes the receiver..Using the yagi,
it's pretty clean. You'd probably see the same thing,
being you are using the same radio...Mine is a mk2g,
but 6m is probably the same appx circuit...Myself,
I don't see a loop really being much better than a
dipole..There won't be any mistake switching to a
yagi... :) MK

The ironic thing is that it often requires some knowledge to be able to tell which effects are fly crap and which are important. I sometimes get the impression that people who offhandedly dismiss certain effects as fly crap don't really have the knowledge to judge. Thinking that the discussion we've been having involves 0.01 dB of gain and milliwatts of coax radiation indicates a lack of understanding of the possible magnitudes of the effects we're talking about.

"Fly crap" is also a very relative thing. Most people are perfectly able to decide what's adequate for their purposes. A person who's 20 over 9 talking to his good buddies, and that's his sole goal, could care less if his antenna is 10% efficient or radiating mostly straight up. To him, efficiency and radiation angle are fly crap, and appropriately so.

That doesn't mean it's fly crap to everybody else.

1386. "Sloshing" EM Energy

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-17 20:48:08 UTC
From: Cecil Moore <w5dxp@hotmail.com>
Message-ID: <42b337fc$1_1@spool9-west.superfeed.net>
Source record: 74752

It has been said that the energy stored in the standing waves
of a transmission line just "sloshes" around.

We can demonstrate standing waves using a laser beam normal to
a perfect mirror. There are points of maximum irradiance and
points of minimum irradiance in the standing waves. So does
the EM energy in the standing waves of light in free space
"slosh" around like the energy in the standing waves in a
transmission line? If so, where does the inductance and
capacitance in free space come from to generate that 377 ohms
of characteristic impedance? If not, then why do the EM waves
in a transmission line behave differently than the EM waves
in free space? What different laws of physics do photonic waves
in transmission lines obey than do photonic waves in free
space? Of the E-field and H-fields rules for EM waves in free
space, which of those rules are violated by EM waves in a
transmission line? Is there one set of Maxwell's equations for
free space and a separate set for transmission lines? Did
Maxwell ever mention the scientific concept of "sloshing"?

The trouble with a 2 or more element yagi is it has to be rotatable.

Simple dipoles and loops do not.

> transmission line?

Yes -- there's energy actively bouncing around in that there beam; if you could reduce it down to one laser burst that was shorter than the distance between the laser and the mirror you'd (in theory at least) be able to see it.

> If so, where does the inductance and
> capacitance in free space come from to generate that 377 ohms
> of characteristic impedance?

They don't. The behavior of EM radiation in free space is described by Maxwell's laws. The 377 ohms of characteristic impedance comes from the permittivity and permiability of free space but inductance and capacitance are only meaningful concepts if you have conductors in your model.

> If not, then why do the EM waves
> in a transmission line behave differently than the EM waves
> in free space?

Because they're bounded by conductors.

> What different laws of physics do photonic waves
> in transmission lines obey than do photonic waves in free
> space?

None. They obey Maxwell's laws.

> Of the E-field and H-fields rules for EM waves in free
> space, which of those rules are violated by EM waves in a
> transmission line?

None.

> Is there one set of Maxwell's equations for
> free space and a separate set for transmission lines?

No, just different boundary conditions to start.

All this is covered in a good college E&M course. I wish I had an E&M book that I could recommend for self-study, but I don't. Mine is "Elements of Engineering Electromagnetics", but I took a course. I don't think I would have been able to just pick up the book and learn it from there.

> Did
> Maxwell ever mention the scientific concept of "sloshing"?

Who knows? And was he talking about light waves or a wee dram of whiskey at the end of the day?

As hard as it may be to believe for anyone who's gone through an E&M course the original form of Maxwell's equations were more difficult to comprehend than the way there're usually presented now -- the vector notation that is currently used either wasn't around then or wasn't in widespread use.

Ooooh! Did I stumble upon a sore nerve Roy? No one in particular was referenced and all names were changed to protect the innocent.

If you feel my example covered, or in anyway was directed towards any of your past or current waltzing on the pin, it is you who fail to understand my previous post.

I was simply pointing out that it is sometimes better to simply put up an antenna, make contacts, and enjoy the fellowship of other amateurs.

The rec.radio.amateur.antenna version of "All My Children" (An American daytime soap opera, by way of explaination, for our British friend Reg) provides endless entertainment, with the occasional bit of useful information. If some may find my observation untoward, mores the pity!

It depends on what characteristics of antennas you wish to examine by
modelling techniques.

Efficiency, bandwidth, tuner component values, effect of ground
electrodes, feedpoint impedances, feedline loss, radiation resistance,
etc. Or just radiation patterns and take-off angles which most people
already know about for simple antennas.

1393. Caculating VSWR from rho and rho from VSWR

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-17 22:18:26 UTC
From: Owen <none@no.where>
Message-ID: <S_Hse.20702$F7.11504@news-server.bigpond.net.au>
Source record: 74760

I note that any textbook I pick up shows that VSWR=(1+rho)/(1-rho) where rho is the magnitude of Gamma (Gamma=(Z-Zo)/(Z+Zo)); rho=abs(Gamma)).

Now, reading TL theory texts can be confusing because of the sometimes subtle swithes to and from an assumption of lossless line (under which rho cannot exceed 1).

Since VSWR is the ratio of the magnitude of the voltage at a maximum in the standing wave pattern to the magnitude of the voltage at a minimum in the standing wave pattern, if we are to infer SWR at a point on a line (if that makes sense anyway) from rho (which is a property of a point on a lossy line), isn't the formula VSWR=abs(1+rho)/abs(1-rho) correct in the general case (lossy or lossless line)?

Given that rho cannot be negative (since it is the magnitude of a complex number), the general formula can be simplified to VSWR=(1+rho)/abs(1-rho).

Seems to me that texts almost universally omit the absolute operation on the denominator without necessarily qualifying it with the assumption of lossless line.

If VSWR=(1+rho)/abs(1-rho), then doesn't it follow that rho is not a function of VSWR (except in the lossless line case where VSWR=(1+rho)/(1-rho) and therefore rho=(VSWR-1)/(VSWR+1))?

Thoughts?

Owen

I would recommend:

Introduction to Electromagnetic Fields, by Paul and Nasar, 3rd edition.
ISBN: 0070460833. Available from www.bn.com, used, from $59. The review of
vector calculus in the first two chapters is excellent. The text covers
plane waves incident on material boundaries (and the resultant standing
waves). It also covers transmission lines.

Regards,

Frank

One consideration is that Magnetrons are NOT designed, normally for ccs service-- they are designed for "PULSE" service, even the ovens- (duty cycle of MUCH less then even .5) and, pulse transmissions arn't looked favorably on many of the microwave bands any more.

A few months ago, I came upon a book that really looks like it might fill the bill: _Engineering Electromagnetics_ by Nathan Ida. The text is clear but doesn't skimp on math or theory. At the end of each section, there are numerous examples showing how the concept is applied in the solution of real problems -- something sorely missing in most other texts and, for that matter, in a lot of college courses. For example, after the "Inductance and Inductance" section in the "Magnetic Materials and Properties" chapter are the following fully worked and explained examples:

Application: Self-inductance of a toroidal coil
Application: Self-inductance of a long solenoid - Inductance per unit length
Application: Inductance per unit length of coaxial cables
Application: Mutual inductance between a wire and a toroidal core - core memory
Mutual inductance between straight wire and loop
Self- and mutual inductances in multiple coils

It's sort of like a Shaum's Outlines and textbook combined, but in a way that you can see the transition from the theory to practice. It's also a good reference to use later on.

And the answers to all the problems (but no details about how they were solved) are at the back of the book.

I was lucky and found a used one at Powell's while browsing in their technical bookstore, but even new it's a bargain.

To complicate matters, roughly half the textbooks use rho instead of Gamma for the complex reflection coefficient. You've got to be careful.

The whole concept of VSWR gets flakey on a lossy line, and really loses its meaning. It's often analytically convenient to define a quantity at a point and call it "VSWR", although in the presence of loss it no longer means the ratio of maximum to minimum voltage on the line. Since it's lost its original meaning, it comes to mean just about anything you'd like. And the generally accepted definition then is the equation you gave in your first paragraph. That is, in the presence of loss, VSWR is something which is *defined* by that equation, rather than the equation being a means of calculating some otherwise defined property.

Under the right conditions and if loss is large enough, rho can be greater than 1, in which case the VSWR as defined by the equation in the first paragraph becomes negative. Again, this is no longer a ratio of voltages along a line, but a quantity defined by an equation. If you alter the equation, you're defining a different quantity. Now, there's no reason that your "VSWR" definition isn't just as good as the conventional one (first paragraph equation). But the conventional one is pretty universally used, and yours is different, so if you're interested in communicating, it would be wise to give it a different name or at least carefully show what you mean when you use it.

> Given that rho cannot be negative (since it is the magnitude of a

Rho is never a function of VSWR. VSWR is a function of rho. Unlike
actual VSWR (that is, the ratio of maximum to minimum voltage along a
line), the reflection coefficient can be and is rigorously and
meaningfully defined at any point along a line, lossy or not.

Indeed. It occurs to me that if one was to try to measure VSWR (say
using a slotted line with probe) on a lossy line operating at high VSWR,
the best estimate would come from finding a minimum, measuring it and
the adjacent maxima and calculating VSWR=(Vmax1+Vmax2)/Vmin/2 so that
the measurement is biassed towards the notional VSWR at the point of the
minimum (the minimum being much more sensitive to line attenuation than
the maxima).

I mean't function in the sense that there is one and only one value of
f(x) for x, rather than in the causual sense.

> actual VSWR (that is, the ratio of maximum to minimum voltage along a
> line), the reflection coefficient can be and is rigorously and
> meaningfully defined at any point along a line, lossy or not.

Agreed.

Thanks for your exhaustive reply Roy, it is appreciated.

What I glean from this is that although Gamma and therefore rho are well
defined, and both are a function of position on a line in the general
case, the "accepted mathematical definition" of VSWR in terms of rho
does not behave well (eg producing a negative value) in some cases and
is not a good estimator of real VSWR in those cases.

It seems fair to say that the reason that the "accepted mathematical
definition" of VSWR does not behave well is that it depends on an
assumption of a distortionless line (Xo=0). (Lossless lines are
distortionless but the converse is not necessarily true).

I take your point about the need to qualify a different algorithm by a
different name.

Thanks again.

Owen

Good response, Roy, but concerning rho and gamma to represent reflection coefficient, I refer you to Reflections, Sec 3.1,

"Prior to the 1950s rho and sigma, and sometimes 'S' were used to represent standing wave ratio. The symbol of choice to represent reflection coefficient during that era was upper case gamma. However, in 1953 the American Standards Association (now the NIST) announced in its publication ASA Y10.9-1953, that rho is to replace gamma for reflection coefficient, with SWR to represent standing wave ratio (for either voltage or current), and VSWR specifically for voltage standing wave ratio. Most of academia responded to the change, but some individuals did not. Consequently, gamma is occasionally seen representing reflection coefficent, but only rarely."

Hope this clarifies any misunderstanding concerning the use of gamma for reflection coefficient.

Incidentally, Roy, I recently mailed you a CD containing Laport's book, "Radio Antenna Engineering." I'm wondering if you received it, or did it go astray?

If you're responding to something you should post things as a followup, even if it's a continuing argument -- saves us new folks to the list some confusion.

Besides, energy in EM waves can and does travel (or "slosh around", if there's reflections) at sub-light speeds, specifically in coax, waveguides and just about any bulk material (including air) that has an index of refraction higher than 1.

Most interesting. I have on my library shelf 14 texts which deal
primarily or in a major way with electromagnetic waves and/or
transmission lines, and two with microwave circuit design. Of those,

8 (including both microwave design texts) use Gamma
4 use rho
2 use K
2 use k

If NIST's pronouncement had any effect at all, it was the opposite of
what was intended -- the four texts using rho were copyrighted in 1951,
53, 63, and 65; the 8 using Gamma were copyrighted in 1960 - 2000, 6 of
them after 1965. So it appears from my sampling that Gamma is becoming
more, not less, prevalant.

> Hope this clarifies any misunderstanding concerning the use of gamma for
> reflection coefficient.

I'm afraid it doesn't, unless my collection is very atypical. I don't
think it is, because it includes many of the classics.

Thanks for the information Walter. I must have a few "rare" texts that
use Gamma (Gamma to mean uppercase gamma) for the voltage reflection
coefficient.

I wonder if the recommendation / standard to which you refer is taken up
in any international standard?

I do note that my ARRL Antenna Handbook (18th edition) and ARRL Handbook
(2000) both use rho, however they reckon that rho=(Za-Zo*)/(Za+Zo)
(where Zo* means the conjugate of Zo). They do this without derivation,
and seem to be in conflict with the derivation in most texts. I suppose
the derivation is buried in some article in QST and in the members only
section of the ARRL website.

Back to notation, accepting that the preferred pronumeral for the
voltage reflection coefficient is rho, is there a pronumeral used for
abs(rho)?

Hi Owen,

From the general use I'm familiar with, rho alone refers to the abs value, while the two vertical bars on each side of rho indicates the magnitude alone. However, following Hewlett-Packard's usage in their AP notes, in Reflections I use a bar over rho for the absolute, and rho alone for the magnitude. However, I explain the term in the book to avoid confusion.

Russ,
There is a SCARS (So Cal Antique Radio Society) swap meet starting at 7AM in a parking lot at 1000 Isobel St. in Burbank if you are interested. Take the Burbank Blvd offramp to Victory (bottom of the overpass) . Turn south on Victory, go one block or so to Isobel and turn rt. The parking lot is on the left side. Enjoy, Mike KF6KXG

Sorry if I am repeating stuff that you may have seen before, but I have
noticed things that do not seem to add up. For example the paper at:
http://www-personal.engin.umich.edu/~mcjz/papers/neculaes_tps04.pdf;
Shows the CW output of the magnetron spectrum as -10 dBm. Since for the
output is monitored via a 30 dB coupler, and a 30 dB attenuator I would have
expected the amplitude to be 0 dBm. It is hard to imagine such testing
being done with a grossly overheated magnetron. Having observed the output
of a microwave oven on a spectrum analyzer, it did appear to be pulsed,
although the spectrum was more characteristic of a frequency hopping (or
swept) signal.

Owen,

There was a big discussion about this last year, and somebody posted that
the ARRL was going to eliminate the conjugate reference.

I wasn't very clear. (actually, not at all clear) on the loop. The
person I was talking to has offered to put up a full sized 80 meter
loop in my yard for HF. I think you are right. i would definitely
like to budget a good pair of filters for the rig. As it stands,
except for 20 and 6, I am tuning an 80 meter dipole for all other
bands.

I do want to create a yagi for 6 meters. I am hoping to get at least
4 elements, but I'll settle for 2 or 3 if necessary.

Just for your info, KM4QQ, Ed, the other party I was talking to last night and tonight made six contacts before realizing it was off the back of his Log Periodic. However upon closer examination, he discovered he was actually on his 80 meter loop. We did some experimenting and discovered he gains one s-unit by using the beam pointed at me vs using the 80 meter loop. He will be using the loop to monitor 6 meters and then rotate the beam as needed.

The principle behind Hooke's Law is only one element in determining the
resonant frequecies of vibrating bodies. Oops . . yeah, I know, that
could be taken . . ah, never mind. Moving along there is no such thing
as a "work hardening law".

What you have is a simple fully restrained fixed end cantiliver beam
with a point mass on it's far end. Your "system" when excited by random
forces like wind impingement loads vibrates *mechanically* at it's
natural freq and it's harmonics which can cover any number of octaves.

Your "system" won't crap out due to vibration unless the skin stresses
in the rod exceed the specific (published) endurance limit of the
material.

"The rest is left as an exercise for the student to bumble thru."

None of which of course has a friggin' thing to do it's characteristics
as an antenna. Which you already knew. Tnx for the troll, gave me
something delightfully useless to do while I finished off this double
magnum scotch 'n water.

> Perhaps I should patent this
> resonant antenna that is almost frequency independent!

Go for it William, you can't miss, the patent office hangs numbers on
any brainfart which comes down the road these days. At worst you'll be
able to claim that you're an "inventor" of record. Brag points are
where you find 'em.

Ditty dah dit dah.

Source record: 74686

You've noted what I've noted before in this forum, if you say that "(V)SWR" is the SWR that would result if the forward and reverse waves at a particular point on the line (the point at which you've measured rho) were allowed to develop a voltage maximum and a voltage minimum (or a current maximum and minimum). I happen to believe that is more in keeping with the original meaning of (V)SWR than the formula which says VSWR=(1+rho)/(1-rho).

Of course, this all gets quickly into people trying to assign physical significance to rho which is not really there; they get confused when rho>1.

If you are clear and consistent with your definitions, I don't see that any problems result either way. I happen to believe that the formula you came up with is a better one than the one you commonly see in texts, but I also agree with Roy that you'd better be clear about it if you use it, because it goes against the commonly accepted grain. On the other hand, I've seen texts that derive it in the same way you have, which come up with the "wrong" answer (without the abs) based on their initial premises.

Cheers,
Tom

If you think about exponential decay along the line, the geometric mean
sqrt(Vmax1 * Vmax2) would be an even better replacement for Vmax, to use
in the numerator, than the arithmetic mean (Vmax1 * Vmax2)/2.

hi,
I am designing a yagi antenna at 2.4 ghz .I am in this antenna business for just past 2 months.I am constantly looking for an appropiate balun design.
Could anybody help me in finding these question-

Which design will suit for my purpose ?(ferrite core/ferrite rod or any other thing?
As per my information 1:1 current balun may suit .Am I right ? If yes then any other specification about it ?
where can I find complete DESIGN DETAIL about this perticular balun (this is a bigger problem for me).

I want to request all antenna studs ,please help me. I have just 10 days to finish this project.

Regards,
Gaurav jain

Another problem that needs to be fixed is the difference between
the "virtual" rho and the physical rho. What is rho looking
into point '+' from the XMTR side?

XMTR---50 ohm coax---+---1/4WL 75 ohm coax---112.5 ohm load

The physical rho is (75-50)/(75+50) = 0.2 which is the same
as 's11' in an S-parameter analysis.

The "virtual" rho is SQRT(Pref/Pfor) which, in a Z0-matched
system is zero. (The 50 ohm coax "sees" a V/I ratio of 50 ohms)

Rho, looking into the load, is (112.5-75)/(112.5+75) = 0.2.

The virtual rho, looking back at point '+' from the load side
is |1.0| but that same reflection coefficient, s22 for an
S-parameter analysis, is (50-75)/(50+75) = -0.2.

Let us know if it says anything about "sloshing" EM wave energy
including reflected light waves in free space.

Confusion reigns.

Four years ago in another thread I posted thus:

Quote

On Mon, 12 Feb 2001 15:25:28 -0800, Roy Lewallen <w...@eznec.com>
wrote:

>Just a point of clarification. Rho in these equations is the magnitude
>of the reflection coefficient, not the reflection coefficient itself.
>The reflection coefficient is actually a complex number. Rho is
>unfortunately used to sometimes represent the (complex) reflection
>coefficient and sometimes (like here) its magnitude, although some
>people (me included) prefer to use uppercase gamma for the complex
>reflection coefficient and lowercase rho for its magnitude.

Roy raises a good point. Tom Bruhns already took me to task for a
somewhat careless use of rho. Although I did define it below, as Roy
and Tom said, it is often used as a complex number.

I too prefer upper case Gamma for the complex number and rho for the
magnitude but unfortunately the literature is full of confusing usage.
Some of the literature was even published by Tom's employer, the
former H-P, now Agilent (how do you pronounce that again?)

My autographed copy of Steve Adam's, book "Microwave Theory and
Applications", published by H-P, shows on page 23:

" |Gamma| = rho "

Similarly, my handy dandy H-P "Reflectometer calculator" sliderule
says that SWR = (1 + rho) / (1- rho) which bears a striking
resemblence to what I wrote below.

But then in H-P's App Note 77-3, "Measurement of Complex Impedance 1-1000 MHZ", it says that rho is a vector quantity and it shows:

SWR = (1 +|rho|) / (1 - |rho|)

Finally, the best reference I have is General Radio's "Handbook of Microwave Measurements" (out of print but reissued by Gilbert Engineering) and it says that Gamma is complex and rho isn't.

End quote.

The slotted coax balun would be an option. I don't have a ready
reference, but you might look for the NBS standard gain antenna, as it
uses such a balun.

Also here is another possibility:

http://www.atnf.csiro.au/projects/ska/techdocs/SlottedCoaxBalun.pdf

you could use a gamma match that requires no balun. or you could use a T match with a 1/2 wave phasing line that acts as the balun.

Hi Harold,

Then it takes a breed of fly-herder to round them up, and -um- milk
them, so to speak. Otherwise this thread would have long ago died
without that fertilizing contribution.

There must be a market for a high priced, exotic specie of pepper
being sold - what a difference labeling can make. I remember one of
my sales buddies pointing out how Jack-in-the-box could have emerged
faster from their health fiasco a dozen years back:
"We cook the shit out of our burgers."

It seems I've seen a similar appeal being made here.

The industry (the people who serve only to sell you what "you want")
must think we don't have enough feces in our diet. They've asked the
government for approval to Nuke food to kill germs. The upshot is
they would keep things less clean and you might have to pick your
teeth more.

These things are just little things. Industry would make similar
arguments of scale. Think about it the next time a bite into a burger
hits bone.

Hmmm. Since the dipole is going to be about 1.4 inches long, how do
you propose to do this?

You might also consider a loop Yagi.

http://cheatthezone.tripod.com/wireless/loopyagi.html

Google for others.

The loop has a "built-in" balun.

The TRW [now Northrop-Grumman Space Technology] is stil around - on
the last Saturday of each month so this will not work for Russ on this
weekend. There are Ham Radio Outlet stores in Burbank and in Anaheim
and Jun's Electronics in Culver City. I only know of one electronic
surplus outlet, ALL Electronics which I recall being in Burbank - been
there once and it wasn't worth a return trip for me, nothing I
couldn't get elsewhere or via online ordering.

I suggest you may have more fun by spending part of the afternoon in
Venice (in between LAX and Santa Monica) and take a walk along the
'boardwalk' (improperly named as it is concrete) and enjoy the
outrageous people. You'll find all sorts of colroful folks hawking
anything from sunglasses to magic beans, perhaps see the chainsaw
juggler and see body art that could make you cringe. It is an
interesting study in sociology and you can enjoy today's clear skies,
warm temperatures, ocean air and thong-clad SoCal beauties.

Howard

Etch it on pc board. Come to think of it - at that wavelenth - simply etch
the entire antenna on a board.

Isn't 'frequency independent' and 'resonant' appearing in the same sentence an oxymoron? Just like 'sanitary sewer'? One thing's for sure, just being an oxymoron won't stop the patent office from granting a patent. Go for it! The examiners at the patent office won't even know whether the antenna is resonant mechanically or electrically.

With an attic dipole installation is it worth putting snap-on ferrites
on AC wiring or other low voltage (phone, network) cabling that's nearby?

>
==========

Electrons sloshing about in conductors, in the same general direction, always attempt to avoid each other.

This unsociable characteristic results in a pressure which drives them to flow near to the surface of conductors in which they are sloshing.

Hence skin and proximity effects.

There is an opposite effect. When electrons slosh about in opposite general directions they form a great liking for each other.

The result is a mechanical attractive force between a pair of parallel conductors carrying current in opposite directions. Also another proximity effect.

It's all so simple. Can't imagine why you have sloshing problems. But no doubt Cecil will introduce reflections, standing waves on meters which don't measure them, and SHF scattering parameters. ;o)

How about I just introduce photons? EM waves are photonic energy
whether they are traveling in free space or in a transmission
line. How do the photons slosh around? The electrons that slosh
around are the carriers of the EM wave and are not the EM wave.

Who has published a scientific paper on photon sloshing?

Cecil, W5DXP wrote:
"If so, where does the inductance and capacitance in free space come from to generate that 377 ohms of characteristic impedance?"

First, impedance is a voltage to current ratio as in Ohm`s law. It can be complex if reactance and resistance are involved, but it`s still a voltage to current ratio. Antennas radiate power which has the units of watts, and from the expanding radiation wavefront in free space, this amounts to watts per square meter.

A wire one meter long placed for maximum excitation when swept by the passing wave will have a voltage induced across it equal to the wave`s signal strength in volts per meter.

There are no volts or amps in the wave, only the ability to generate volts and amps in conductors.

The 377 phms of characteristic impedance is the ratio of the electric field strength to the magnetic field strength in the wave. Its purpose is to get the units right. The ratio of energy in the electric and magnetic components of the wave is really one to one. It is really the same energy swapped back and forth between the electric field and magnetic field which physically are at a right angle and both are at right angles to the direction of travel.

Kraus has done the math for us on page 170 of the 3rd edition of "Antennas". His answer is 376.7 ohms, a pure resistance. This is the far field in free space.

Best regards, Richard Harrison, KB5WZI

The slotted coax balun that I suggested is a viable possibility.

The half-wave balun that you proposed (I suspect before you actually
noted the frequency) is not. The application cries out for semi-rigid
coax and bending that half-wave balun without exceeding the bend
radius limitation is an issue. Similar problems lurk with a gamma
match which is lousy at vhf and would be a really bad idea at 2.4 GHz.

IMHO, designing and building a Yagi at 2.4 GHz is a bad idea from the
beginning but I assume the OP has an assigned project and he's stuck
with it. If not, he should be building a horn.

Designing one on microstrip is an even bigger can of worms. (An
American idiom similar to Pandora's Box)

Les Besser agrees with the ARRL Handbook except he
uses gamma for the complex reflection coefficient:

gamma=(Za-Zo*)/(Za+Zo) (where Zo* means the conjugate of Zo)

But for most practical calculations, the Zo is assumed to
be purely real, so many texts give gamma=(Za-Zo)/(Za-Zo).

rho=[gamma]=absolute value of gamma=magnitude of gamma

Rho can never be greater than one going into a passive
network. Only when you have an active device, or gain, can
you move outside of the unity circle on the Smith Chart.

I have been working on the BPL Interference issue.

One of my projects has been exploring ways by which ordinary (well, competent anyway,) amateurs can make reasonably reliable measurements of noise / interference using existing amateur station equipment or equipment that is easy for amateurs to construct.

This has led me to search for a portable antenna of reasonably predictable gain that can be used with a known HF SSB receiver.

I have had a hack at predicting the gain and antenna factor of a small square untuned loop driving a 50 ohm load. The model is in a Mathcad worksheet, but I have copied it to a gif file which you can view on my website at http://www.vk1od.net/bpl/loop.mcd.gif . (The worksheet is entirely in metric units.)

I would appreciate any comments / review on the model and calcs.

Looks pretty decent, until the very end. Antenna Factor (AF) is the ratio of the field strength voltage to the output VOLTAGE, not power, although you did get the numbers right.

So practically, since the average ham has a receiver with a sensitivity in the order of a microvolt, then your antenna limits your minimum discernable signal level to around 65 uV/m. Maybe 100 uV/m to be on the safe side. That's likely quite adequate for detecting BPL noise, but the real problem is having the average ham get an anywhere near reasonably accurate measurement of 100 uV. Your S meter just isn't good enough, so now you're moving beyond the "average" ham's capability. Accurizing your receiver into an RF microvoltmeter is a tough task, so maybe the best route is to use a signal generator as a comparison standard. Old boatanchor signal generators in the 7 MHz region are reasonably available, and their attenuators are a lot better than their frequency stability and portability. <g>

I applaud your goals, but getting data accurate enough to toss into an intelligent argument about BPL is a tough task. Good luck.

I have looked at it and I can't see that I said "power" in relation to
Antenna Factor. Perhaps I am blind. (You didn't confuse the units dB/m
(dB per meter) with dBm (db wrt 1mW) did you?)
>

In fact, the technique calls for measuring signals on the rx from the
noise floor to about 20dB above it. The noise floor for receivers today
is typically -135dBm.

> lot better than their frequency stability and portability. <g>

No, the technique does not use an S-meter. In a nutshell, it uses Ed
Hare's (W1RFI) technique for calibrating the noise floor of the
receiver, using an external attenuator to keep the rx input below the
AGC threshold, and measuring the audio output with signal and the audio
output from rx internal noise as inputs to a calculation of the input
signal power. Applying external attenuator losses, feedline losses and
antenna factor allows calculation of field strength.

> I applaud your goals, but getting data accurate enough to toss into an
> intelligent argument about BPL is a tough task. Good luck.
>

I have gotten sidetracked here, my real interest is the completeness /
accuracy of the loop model.

If you find yourself short of sensitivity, try a tuned loop in the
style of a magloop and match the antenna to the receiver.

But whatever you adopt, accuracy will be limited by the uncertainty in
the amateur's receiver input impedance. This will change from band to
band and its actual value will be a matter of guesswork.

A receiver's input impedance can be masked with an attenuator. But
this further reduces sensitivity.

With amateur grade equipment, facilities and environment, expect a
measuring uncertainty in the region of 4 to 7 dB at 7 MHz. Which is
good enough for most amateur purposes and makes your precision
calculations, including conductor diameter and conductivity, not worth
the trouble.

All you need for calculation is enclosed loop area, loop inductance,
receiver impedance and a pocket calculator.

The uncertainty of a measurement is just as important as the value
itself. The only way to assess uncertainty is to compare with
professional-grade equipment. In which case, if professional grade is
obtainable, you can dump the amateur stuff.

I do like the way your calculations appeared on my screen with one
mouse click.
How do you do it?

Reg.

In the BPL report at
http://www.ofcom.org.uk/research/technology/cet/powerline/ascom.pdf
I noticed the system noise floor at about 10 dBuV/m (in 9 kHz). For the
tests they used an active bi-conical antenna. (By my calculations 10 dBuV/m
is about 9 uV(2.5 kHz BW) from a 40 m dipole at 7 MHz.) In the previously
mentioned report most of the BPL signals -- even at 1 meter from the
source -- is < 60 dBuV/m. It seems your system with the loop will be much
less sensitive at about 100 uV/m (+40 dBuV/m).

Incidentally, when I attempted to save your web page of math, it was saved
as an ".mcd" document. Obviously I was not able to open it with Mathcad,
but will have to type it in by hand.

Might be interesting to replicate your results with NEC2.

I did my best with this same issue a year or two ago, and in the light
of what transpired then I suggest you not waste your time, Tom! The
easiest way to see that (under very special circumstances) rho can
exceed 1 in a passive network uses a simple geometrical argument*.
Unfortunately geometry has even less attention paid to it today than it
did when I was in high school.

*Tradition has it that words translatable as "Let no one ignorant of geometry enter" were written on the door of Plato's Academy. This is probably not true, though Plato certainly had a high opinion of geometry. See

In concert with an SSB rx of noise floor -135dBm in 2KHz Effective noise bandwidth (they are realistic figures for an IC706IIG for example), the rx noise in 2KHz BW is 0.04uV. With an antenna with AF=36dB, the rx noise floor translates to field strength of 2.5uV/m or 8dBuV/m.

Clearly, the "instrument" is not going to be suitable for measurements below 11dBuV/m. However, measurements of the BPL systems on "trial" here (Mitusbishi based on DS/2 45Mbps chipsets) showed field strengths of 45 to 65dBuV/m in 2Hz and a rx with this loop needs 20+dB of RF attenuation to keep the interference below the AGC threshold (with the benefit of stabilising the rx input Z somewhat).

> But whatever you adopt, accuracy will be limited by the uncertainty in
> the amateur's receiver input impedance. This will change from band to

Yes, I have been measuring the rx noise floor with 20dB of attenuation to simulate the common measurement configuration.

>
> A receiver's input impedance can be masked with an attenuator. But

Given that the interference is 70dB above the ambient noise floor, we don't need 1/10dB accuracy to demonstrate to regulators that there is a problem

Understood. My view is that if professional grade EMC measurement kit is
available, we can use it to do a lower grade calibration of the amateur kit.

>
> I do like the way your calculations appeared on my screen with one

The model is in Mathcad, I copied it to the clipboard and pasted it into
Frontpage (my web editor) which finds only a useful format in the
clipboard and saves it as a GIF file (ie a graphics image).

Thanks for checking the model Reg, I think you are telling me it is more
precise than needs to be, but you haven't faulted it for accuracy.

Source record: 74582

We did some
experimenting and discovered he gains one s-unit by using the beam
pointed at me vs using the 80 meter loop.

Not unusual really...The big HF antennas have quite a
bit of gain in some directions...Some other direction,
it might be a dud though...Wonder how much gain his
"log" has...Most are fairly average, being they are
covering a pretty wide range. On the other hand,
my 3 el is set up for maximum gain..About 9.4 dbi,
or about 7.25 or so dbd. He may have that much gain,
if he has quite a few elements. I'm probably getting
more bang per buck per pound of metal, at that one
frequency...I often talk off the back and sides.. I don't
have a rotor. If I need to turn it, I have to go out and
"armstrong" the mast...So I note the skip trends at the
time, and turn it that way. Usually east in the early day.
Often later, as the skip drifts west, I'll end up swinging it
around in the evening. Most lately is E skip...Here at this
qth, the HF antennas have gain also, but they are fairly
unusable due to the trashing of the receiver. On the 706,
the yagi really cleans it up. This is probably worth more
here, than the transmit gain. My usual parallel dipole setup
for the low bands is resonant on 6m pretty close. I don't
even need a tuner , if I remember right...I'm sure it's got
some pretty good gain in some directions. But the beam
still smokes it overall. I actually don't get on there all that much,
as I usually don't notice the band openings, and have been
busy also...But all the people I've worked so far gave me
really good reports. I did do a f/b test with it , right after I
built it, and it seemed to jive with the model almost exactly.
Or as far as I could tell with my limited, means of
measurement...The beam is an exact copy of the NBS
yagi in elnec/eznec. MK

Yes, Fig 8 shows about 10dBuV/m in 9KHz which interpolates to 5dBuV/m in 3KHz, and their measurements used a peak detector. On white noise, the QP value would probably be 2 to 3dB lower.

I have made a large number of measurements at my home QTH (in a residential neighbourhoos) using a half wave dipole and assuming an average gain of -1.2dBi or an AF of -11.6dB/m and I regularly get ambient noise readings down to around 0 to 3dBuV/m QP in 3KHz or extrapolated to 9KHz BW, 5 to 8dBuV/m QP. Ambient noise is probably lower than indicated by ITU P372-8!

See my response to Reg re the noise floor for the setup, I make it around 8dbuV/m or 2.5uV/m. I don't pretend it can measure ambient noise, but it can and has measured BPL interference at 40dBuV/m to 70dBuV/m.

> Incidentally, when I attempted to save your web page of math, it was saved

No you won't, I have posted a later version of the mathcad file to http://www.vk1od.net/bpl/loop02.mcd .

The file you downloaded is an image (.gif) called loop.mcd.gif, and it looks like your download process dropped the extension, or you hide the extension on your machine. (Some software thinks that the first dot begins the file extension, whereas it is the last dot that does so.)

>
> Might be interesting to replicate your results with NEC2.

I have modeled the loop in EZNEC and get very similar inductance and resistances.

Thanks Fred, appreciate the review.

Dunno....You never know what will happen. Will
usually vary per freq...One freq might do nothing,
and another trash everything you have...Myself,
I have a 40 dipole in the attic , fed with 300 ohm
line to a tuner, but I use it so rarely, I didn't bother
with any of that...It's just a backup, and bad wx
antenna...Myself, I probably put up the antenna, and
try it. If it trashes something, I'd concentrate on those
wires first. You never know...You might get lucky and
not need much. But...if you gotta lot of beads around,
and want to try preventive beading , while you install
the antenna, I could you could. Wouldn't hurt anything..

One of the most serious sources of error will be pick-up on the long line between the small loop and the receiver. With a coax line there will be a greater signal pick up on the coax braid than there is in the loop. They are both located in the same field.

So best to use very low impedance balanced pair line such as 50 ohms perhaps with a screening braid. A good choke balun or a 1-to-1 wound transformer would be advisable between the line and receiver input.

Also, depending on frequency, length and impedances, there may be standing waves on the line which could make a mess of your calculations.

A change in line length is a good way to check for errors of this sort.

Fortunately, field strength measurements are seldom needed to great accuracy. Strength is usually required only to be less than or greater than some specified value and there is an ample margin for error.

Personally, I think a tuned loop, in the fashion of a magloop, is a better bet. With its small coupling loop the main loop can be completely isolated from the line and the line can be ordinary coax which matches a 50-ohm receiver.

A tuned loop is far more sensitive than the untuned variety. But its operating frequency range is somwhat restricted.

Field strength measurements are essentially power level measurements and, ideally, the pick-up loop should be impedance matched to the receiver. Result : no reflections.

Reg.

Agreed. Because of the inherent balance of the whole loop I have use a "Voltage Balun", see http://www.vk1od.net/bpl/loop.jpg . I have made observations of the received signal level when close to aerial telephone lines carrying ADSL and the pickup level seems the same no matter which side of the loop is nearest the aerial line.

> Also, depending on frequency, length and impedances, there may be

I have made the assumption that the line is adequately terminated in 50 ohms (the attenuator, and there should be now standing waves. Doesn't that seem reasonable?

Noted.

I have encouraged another ham friend to design an active loop with an AF good enough to get the system noise floor below -10dBuV at 7MHz. That

is another alternative, and it has issues I know.

I am also considering trying to measure the performance of a portable short dipole such as a buddipole (http://www.buddipole.com/) for the purposes of measurement down to ambient noise and a little lower.

> Field strength measurements are essentially power level measurements
> and, ideally, the pick-up loop should be impedance matched to the

But if the rx terminates the line, does it matter whether the "generator" impedance is matched? (I am not trying to bait anyone here, but Reg, I think I understand the standing wave issue you are raising, but my reasoning is that if the rx terminates the line sufficiently well, then standing wave ratio will be small and the error contribution negligible.)

(I think the lights have gone out on the other side of the big pond.)

Owen,
I gather you are interested in measurents only in the 40m band which makes life easier. The photograph of the loop and line makes it more clear what you are up to.

Yes, there will be no standing waves on the line if the line Zo is equal to receiver input impedance. (I didn't make myself clear). If a balun is used it doesn't matter much what Zo is, provided the balun has the correct ratio. So it is necessary to know what Zo actually is just as accurately as the input impedance is known.

With your setup it is impossible to match the loop to the line. But if it WAS possible (eg., as with a magloop) it would NOT be to prevent standing waves.

Your calculations take the loop/line mismatch loss into account. Its only a few dB.

Incidentally, have you considered what effects increasing the number of turns to 2 or 3 would have? They MIGHT possibly be beneficial. It needs more calculations. As with just increasing the size of the loop which almost certainly would be beneficial.

You have set yourself a most interesting and useful task. I wish you well with it.

==========

Yes, Rho CAN exceed unity when the termination is a passive network.

For example, when on a real line, Zo = Ro - jXo and the termination Zt = Rt + jXt then Rho can exceed unity.

Rho has an absolute maximum value which approaches 1 + Sqrt(2) = 2.4142 which occurs when the angle of Zo approaches -45 degrees and Zt is purely inductive.

It arises because of a weak resonant effect between -jXo and + jXt.

The angle of Zo of real lines always becomes more negative as frequency decreases. Mr Smith's Chart does not recognise this. He did it knowingly and deliberately. There are other departures from reality. But at least it is fit for its few intended purposes.

At a previous house, I had a 10 meter attic dipole that made the whole
house come alive when I keyed anything -- had to take it down. On the
other hand, I had an R5 vertical on the roof, just a few feet away
from the same wiring, and it did nothing to the wiring.

Your best bet is to just put the antenna up, see what happens, then
try any corrective actions, if any are needed.

Thanks, Richard. The question was somewhat rhetorical and was aimed at the people who believe that EM wave energy "sloshes" around in a transmission line between the inductance and capacitance in the transmission line and that there is really no forward EM wave energy or momentum traveling at the speed of light and no reflected EM wave energy or momentum traveling at the speed of light.

So I provided a mental example of a laser beam with reflections demonstrating standing waves in free space. Except for the wavelength, all field conditions are similiar to an RF transmission line with standing waves. So how does the light energy "slosh" around without the inductance and capacitance in free space?

Walter Maxwell wrote:

> Cecil, define 'sloshing.'

Hi Walt, I'm having trouble with my news-server so I am posting from Google using procedures to which I am not accustomed.

The classic wave reflection model indicates that forward power travels from the source to the load where it is incident upon the load. At a load mismatch, some of the forward power is rejected and travels back from the load toward the source as a reflected wave. For instance, in the following lossless example, we have 104.17 watts of forward wave and 4.17 watts of reflected wave on the 75 ohm line. This is all in line with "Reflections" and my unpublished article.

100W--50 ohm line--+--1/4WL 75 ohm line---112.5 ohm load

As I infer/understand what Roy, and others, have said while objecting to the material in my unpublished article:

The only real forward power wave is the one that is dissipated in the load. The reflected power wave doesn't travel from the load back toward the source and the extra 4.17 watts in the forward wave doesn't travel from the match point back toward the load. The energy associated with the reflected waves just "sloshes" around in the transmission line and doesn't move very far or very fast and certainly not in the form of EM wave components.

So Roy's use of the word "slosh" in the context in which he used it, is all I can give you. Roy hasn't defined the word and neither has the IEEE. :-)

Thanks Reg, you beat Tom to it. [g]

This was beaten to death (well, I guess it *wasn't* beaten to death,
here it is again) over and over again.

Chipman in section 7.6 "Complex characteristic impedance" deals with
this and concurs with what Reg says above and below.

I think if you check the ARRL Antenna Handbook..you will find something on 4 wire lines. As I recall..the impedance is around 200 ohms..(nominal) as compared with 400 to 600 ohm z of parallel lines..so ..I guess..the impedance is lowered by a factor when using 4 lines (in a square)...Im going by memory..so dont take this as solid facts.

Isn't it the same principle as a capacitor in a resonant circuit
being able to develop a higher voltage than the voltage incident
upon the resonant circuit?

1485. grounding for a long wire antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-19 16:33:49 UTC
From: ineverlookatthis@yahoo.com
Message-ID: <1119198829.932598.198910@g44g2000cwa.googlegroups.com>
Source record: 74601

I would appreciate some advice on grounding for a long wire antenna.

I am just thinking about setting-up my new QTH mainly for 40m and 20m. I would like to try a longwire (around 100m long) with an SG230 ATU, largely because I have an opportunity to sling a long wire high and clear. But how important is orientation of grounding elements? I could bury wire under a small lawn (10m x 10m) but it would lie under just a fraction of the feed end of the longwire. Is this workable ? Alternatively (or additionally) I could run a long wire (again around 100m) in a straight line just beneath grass but at almost 90 degrees to the antenna. I could also connect the far end of this long ground wire to a big galvanised steel fence that runs for almost a mile, I guess that would make a great counterpoise??

What do you guys recommend

Thanks

>I have gotten sidetracked here, my real interest is the completeness /
>accuracy of the loop model.

I have observed that your Mathcad design is short of providing
something of a self-check feature. No where in any of your formulas
do you use Units.

Yes, you label them as notes, but this is risky and has been revealed
in your first comments in response to Ed's comment:
>> Looks pretty decent, until the very end. Antenna Factor (AF) is the ratio of
>> the field strength voltage to the output VOLTAGE, not power, although you
>> did get the numbers right.

Folks who follow your math work, will be skimming it, and perhaps a
few will be transcribing it while others will have picked up your MCD
file. This is to say, very few will actually go the whole distance
for a sanity check.

That sanity check is to include the Units within the formulaic Mathcad
expression; that is, after all, one of the boons of using this
package, otherwise any spread sheet would do as well. This inclusion
would enforce a strict compliance with keeping every transformation
accurate, and you would not end up mixing terms which is very simple
to do - and later suffer from. Cecil's work with Photonics suffers
from this problem horribly such that expressions of power end up in
terms so bizarre and thoroughly out of whack that anything could be
proven, except the proof.

Hi OM,

A small set of radials (8 - 16) planted just into the soil of that 10m
x 10m patch would be adequate. Being under just a fraction,
presumably it would be under the fraction that is closest to Earth -
hence the significant fraction.

Wes Stewart wrote:
"Go ahead Tom, you have the honor. "

It's not worth the effort, Wes. He wasn't willing (or perhaps he was just unable) to do the math last year, and I suppose he isn't this year either. He was willing to call me a liar instead of getting ahold of Besser himself and verifying that Besser long ago corrected that typo about using the complex conjugate in the formula for reflection coefficient.

Anyone willing to start with the very basic idea that forward and reverse waves on uniform TEM lines are independent and the ratio of voltage to current in each of them is equal to the line impedance, plus a few other elementary ideas like the sum of currents into a node is zero can, with a bit of algebraic facility, verify the derivation of reflection coefficient expressed in terms of line and load impedance. Or, they can look in the archives (via Google, etc.) to see it presented in past threads here.

Cheers,
Tom

If Rho (or Gamma) is treated as being a magnitude with an angle which, as one moves backwards along the line, may fall in any of the four quadrants, all those futile arguments about whether or not to use Z or Z* fall by the wayside.

Just proceed with calculations in the normal, mathematically legitimate manner and you will arrive at the correct results or conclusions.

If you disagree with results or conclusions, and there are no mathematical errors, then it is YOU who must be wrong. It's all part of the learning process.

And the magnitude of Rho CAN exceed unity.

Reg.

1490. Antenna Impedance Measurements

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-19 17:48:24 UTC
From: Walter Maxwell <walt@w2du.com>
Message-ID: <ldite.3130$mD6.668@fe07.lga>
Source record: 74606

Quite some time ago, for the purpose of determining the effect of ground on the terminal impedance of a dipole, I measured the terminal impedance of a center-fed dipole, length 32.33 ft. at frequencies every 50 KHz from 14.0 to 15.0 MHz, at heights of 0, 1, 2, 3, 4, 5, 8, 10, 12, 14, 16, and 22 ft above ground. A total of 252 individual measurements.

The equipment used for the measurements were a calibrated 40 ft RG-58 feedline, [calibrated for electrical length and attenuation at frequencies f(x)], a balun consisting of 100 #73 beads over a 2 ft length of RG-303 coax (included in the feedline calibration), a General Radio GR-1606-A RF impedance bridge, a Ferris Microvolter 70B signal generator, and a Collins 75A-4 receiver.

The input impedances appearing at the input of the feedline were then transformed using the W2DU software program 'LINTRNSA' to obtain the impedances appearing at the dipole terminals. (LINTRNSA appears in both the 1st and 2nd editions of Reflections.)

The total data includes the R and X components of the impedances appearing at the input of the feedline, the values of rho and swr at both the feedline input and at the dipole terminals, and the R and X components of the dipole terminal impedances. A total of 2016 data points.

All of the data listed above is in tabular form, ready for putting into a PDF file for use by anyone who is interested in reviewing the data. The data is presented in the same format as in Reflections, Tables 15-4, 15-5, 20-1, 20-2, etc.

If anyone is interested I'll make the PDF file, and I'll be pleased to send it to all who would like a copy. Just give me a jingle (via email, that is at walt@w2du.com.

Hi Myles,

Both. For purposes of feeding it, the proximity of other conductors
and sources of loss, the antenna is as close as that 20' you offer.
On the other hand, for purposes of propagation, your antenna will act
like it is elevated 175'.

Your experience, compared to others, will fall somewhere in between.
Personally, I would think you have a very nice situation. If you seek
to improve it, it would only be in shades of a degree, not in leaps
nor bounds.

Hi Walt,

Your interpolation is by far and away going to be superior to ANY
method Reg has to - well, I was going to say offer - but, Reg, you
have never had any method to offer, have you? You have sort of
mumbled on about mud in the kitchen sink, and averred to secret
recipes, but your limited experience with English garden soil is
rather inconsequential.

Walt, put me on your distribution list for those results. My copy of
your book is in other's hands.

And a liar you still are, apparently.

Besser has NOT corrected it, because it isn't
a typo! The ARRL also agrees.

I recently put up a "long wire" for 20 meters -- three quarter waves
long -- had a high swr & key clicks, but brought it under control with
a single elevated quarter-wave radial, attached to the tuner ground
and going out the window, tacked to the house siding.

Quarter wave elevated radials may do the same for you, or you could
experiment a bit...

Thank you, Owen. Les Besser agrees with the
ARRL.

However, in almost all practical calculations,
Zo is purely real, so that gamma=(Za-Zo)/(Za+Zo) is
used in most texts, and the results are the same.

Point of fact: in the current 20th edition, dated 2003, it has gone.

It had been correct; then they incorrectly revised it; now it has been
corrected again.

Nope, "purely real" requires a special expensive line. I
forget what they call it. Ordinary feedline is not purely
real however close it might be.

Guessed it was something like that.

>> Might be interesting to replicate your results with NEC2.
>
> I have modeled the loop in EZNEC and get very similar inductance and
> resistances.

Now this is where it gets interesting, and hope I can learn something from it, as I am sure I have made a mistake someplace. I have not directly attempted to verify your math, so don't know if you developed it from first principals or got it from a book. I have a number of references including Kraus' "Antennas", and also a text by Stutzman and Thiel, etc., so may try to replicate your methods later.

Using NEC2 I set up a 40 m dipole in free space, and fed it with 1 kW (for nice large current values in the loop). I placed a square loop, 0.5 m per side and 40 m distance. with the plane of the loop parallel to the axis of the dipole, also two sides parallel to the dipole. The dipole uses perfect conductors, and copper for the loop, with 0.7 mm radius conductors. The segmentation of the loop is significantly different than the dipole, but thought it not important because of the large separation of the two antennas. In the loop I am very close to the minimum segmentation allowed in NEC at 0.001 wavelengths per segment -- i.e. 11 segments per side. One segment, near a corner, has a 50 ohm load.

As is easily verified, the field strength from the dipole, at 40 m, is 5.5V/m (RMS). According to NEC the current in the loop varies from segment to segment, ranging from 0.1 mA (peak), to 0.3 mA (peak). I took the average (0.191 mA peak), and computed the RMS average current in the loop. Multiplying by 50 ohms, gives me an output voltage 6.76 mV RMS.

The antenna factor is therefore 58 dB. Wonder if anybody has any idea where the error lies. I have copied the code below.

Regards,

Frank

NEC Code:

dear Richard

thanks very much you set me straight.

I do ponder what i'd have to do (antenna wise) to get a significant
order of magnatude like perhas 200% ie 6db?

i guess going from dipole to a large beam would be significant in
comparasion

but what do you do when you want a bit more than a typical single beam
gives you? stack/co phase 2???

(naturally i am not counting amps of anykind here)

thanks all

and Rich , thanks

Not necessarily, but the exploration of the loop has been done on lower HF, and it happens that the BPL system that I have available for measurement radiates on 7 and 10MHz in low HF.

7MHz is not the only band affected, these guys will use every scratch of spectrum and power to maximise the speed / reach profile of their service.

...

I did.

It obviously increases the open circuit voltage. It also increases the loop inductance, and this almost completely offsets the increased open circuit voltage in terms of power delivered to the receiver input depending on frequency). Calculation of the wire loss resistance becomes more complex due to proximity effect, but that doesn't matter too much because the dominant factor in determining the source Z is the inductance of the loop, and even if tuned, the resistance is small wrt the load.

Ofcom had the answer to measurements down to ambient noise level, the antenna is shown in their recent reports on BPL radiation measurements. However, it isn't a very portable answer.

As I said in an earlier post, an active loop and a portable short dipole (such as the Buddipole) are avenues for investigation.

(A tuned loop obviously helps, but with the single frequency / calibration issues.)

> You have set yourself a most interesting and useful task. I wish you
> well with it.

Thanks Reg, and I appreciate your help with the task in this discussion / review. Wish Amateur Radio well with it, because BPL is the greatest risk to HF Amateur Radio that we have known. I don't say that from having read or heard somone else's reports, I have stood on the streets where BPL is deployed and measured it.

Though my measurement methodology has progressed from "calibrated S-meter" readings, the calibrated S-meter is a reality check, and when I last visited the trial site, set the receiver up and waved the 0.5m sq loop (~-50dBi) about to see if they were still "on air", S-meter readings of 5uV says they are, and it is seriously high in level.

Ofcom's recent reports are a great read, and it looks like they are taking a sane approach at this point, differently to the fervour for BPL expressed by Powell when at the FCC.

I better stop at that, I am getting OT!

Owen

Point of fact: If Zo is purely real, then
Zo*=Zo, and so both forms are correct in this case.

I don't care how much it costs, your line
is NEVER going to be 100% purely real! There
is always a gap between mathematical ideals
and reality.

So i totally agree with you.

But for most practical calculations,
Zo can be considered purely real, and your
calculations will be close.

If you haven't already, you might want to check out what's happening at Spiderbeam http://www.spiderbeam.net/ - - the construction techniques they use appear to hold considerable promise. I'm particularly impressed with the idea of incorporating a 40 meter dipole into their multiband Yagi array, using a Delta-match fed wire connecting the 20m reflector and director together so they act as capacitive hats to bring that short wire to resonance at 7.05MHz. The details of the 40m modification are discussed in the Spiderbeam Yahoo! group.

Hi Reg, it appears you have a copy of the B, L & E's IRE paper reporting their ground radial experiments, "Ground Systems as a Factor in Antenna Efficiency," that the FCC finalized on in the radial requirements for AM BC stations. Their paper was dated June 1937. I knew B (George H. Brown) very well, as he was formerly the chief engineer of the antenna lab of the RCA Laboratories. I also knew L, (Bob Lewis, W2EBS) as well, but only as a ham, because he left the RCA Labs before I worked there. I worked alongside E, (Jess Epstein) for many years at the Labs.

Jess told me why their experiments included 113 radials. It seems that when Jess had plowed in 100 radials he asked Brown what he should do with the wire remaining in the spool. Brown said, "plow it in." There was just enough wire left for thirteen more radials--hence the 113, as reported in their IRE paper.

I attended a radio club meeting where Bob Lewis was a member on a night when Jerry Sevick, W2FMI, was the guest speaker. Jerry was explaining how radials worked. In his blackboard diagram he included concentric wires connected to each radial at various intervals away from the vertical radiator, including at the ends of each radial. I asked Jerry what those concentric wires were for, but he had no answer. Bob Lewis was in his audience, so I then asked Jerry if he knew about the Brown, Lewis & Epstein experiment concerning ground radials. Jerry said, yes, he did. I then asked him if he'd like to meet Bob. He said he certainly would when the time was right. So I told Jerry the time was right right now, and asked Bob to stand. Bob then took the stage, and much to Jerry's chagrin, Bob told the group how radials really worked.

At the end of the meeting a photographer took a picture of Bob, Jerry, and me, that was published in QST sometime in the 60s or 70s, I've forgotten just which issue.

Cecil, W5DXP, quoting others, wrote:
"The reflected power wave doesn`t travel from the load back toward the source and the extra 4.17 watts in the forward wave doesn`t travel from the match point back toward the load."

Users of the Bird and Similar wattmeters know that is what they see. Source and load power is the forward power minus the reflercted power.

Zo of the coax enforces its volt to amp ratio on both the incident and reflected waves. Reflected power is again reflected at the match point because the matched source sees no reflection. That`s the point of producing a match in the load.

Best regards, Richard Harrison, KB5WZI

Yep, that's exactly what I did. Maybe I was looking at your units too fast
and didn't see that "/" in there.

Wouldn't it be better to use a pre-amp at the loop feed? The gain of the
pre-amp could make line pickup a negligible effect, and the pre-amp would
match the coax very well.

Hi Reg and thank you for your advices,

I changed the coupling loop to a length of self suporting wire as you suggested, I turned the trcv on and surprise : it was alive. Tweaked it for a maximum noise on receive.

SWR was/is high so I had to add an antenna tuner. nevertheless, on 14Mhz, cw portion I heard G, ON, LY, LZ, SV, UA, RV, RW, UR, EA, JA, JS.
I even managed to work about all of them. I got kind of weak reports but it's a start. If only I could tweak it so that I get SWR down without the tuner.

> How do you ensure that both are tuned to the same frequency?

I don't. I have no rig for that. I go for the max noise on receive.

What detector do you think should be used to evaluate the interference
potential of BPL?

I had thought that the QP detector was designed to the "annoyance" effect to
AM or SSB modulation. CISPR has standardized this detector, and it's been
adopted for many legal compliance standards world-wide. Yet the USA &
British military insist on use of a Peak detector. Perhaps a dual level is
needed, with a QP value for comparison of harm to the older analog
modulation techniques, and a Peak value, for comparison of harm to digital
modulation techniques.

Yes it is, see http://www.arrl.org/~ehare/aria/ARIA_MANUAL_TESTING.pdf .

That paper outlines the principle of using the known rx noise floor as a
baseline for measurements. I have developed a piece of software for
making the associated audio power measurements and automating the
calculation / documentation process.

Thanks for taking the time to review the loop model, it is appreciated.

Owen

PS: I saw your other response and Richard's suggestion that I use the
units capability of Mathcad. Sometimes the unit capability gets in the
way of readability, for instance I think you could not take the log of E

in volts / meter divided by V in volts and get dBV/m, I think you would need to split E into two variables (say E' and l) and say AF=20*log(E'/V)/l. Additionally, you can spend more time trying to get the units to work, so that they don't collapse to fundamental units of MLT etc, than solving the numerical side of the problem.

But that's only what is printed on the meter scale. It doesn't make the "reflected power" real.

For the (n+1)th time: the Bird so-called "wattmeter" does NOT sense forward and reflected power. It only senses RF voltage and current on the line. The meter scale calibration is a mathematical operation that depends on a lot of assumptions... most notably the assumption that "reflected power" has some physical reality.

I am genuinely open-minded about that debate - which makes the all the more determined to be ruthless about bogus arguments on either side.

And the most bogus argument of all is: "Users of the Bird and Similar wattmeters know that is what they see."

1527. How to measure soil constants at HF

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-20 10:49:54 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <d9670i$9kd$1@nwrdmz02.dmz.ncs.ea.ibs-infra.bt.com>
Source record: 74643

It is fairly easy to measure soil conductivity at DC and power frequencies. See program EARTHRES. Such measurement values apply up to a few hundred kHz.

A few years back I became curious about what happens to conductivity at HF. And at what frequencies does soil permittivity begin to matter. Most amateur activity is at HF and above. Yet, without even thimking about it, we persist in plugging in power frequency values into formulae and computer programs.

A volume of soil between a pair of electrodes behaves as a resistance in parallel with a capacitor.

So this is what I did -

1. Obtain a 16-inch length of galvanised steel tube, 5 inches in diameter. (Mine was industrial ventilation duct)

2. Block off one end of the tube with a rigid disk of plastic insulating material.

3. Obtain a 17-inch length of copper water pipe, diameter = 0.6 inches.

4. Locate the water pipe in the centre of the tube, resting on the plastic disk at the bottom.

5. You now have a coaxial structure of accurately known dimensions. When empty, Zo = 128 ohms. 1/4-wave at 191 MHz

6. Obtain a mixed sample of soil from various places in your garden under your antenna.

7. Fill the galvanised tube in easy stages with garden soil. At each stage compress and pack-down the soil to about the same density as it was in your garden. Make sure the soil is in contact with the inside surface of the tube.

8. Cover the top of the soil in the tube with a flat disk, with a hole in the middle, to discourage evaporation of moisture and drying out of the soil.

9. You now have 16-inch length of transmission line on which you can make HF impedance measurements using instruments as simple as hand-held antenna analysers. Resistance measurements at 50 or 60 Hz can be obtained from volts/milliamps. Although connecting leads can be kept very short it is advisable to correct measurements for lead-length above 10 MHz. Measurements were made up to VHF.

10. Using classical transmission line formulae in reverse, the values of line conductance G, capacitance C and hence permittivity K of the "insulating" material, i.e., the soil, can be calculated.

11. Measurements are of input impedance of the line with the other end open cicuit. The basic equation is Zin = Zo*Coth(A + jB) where A is line attenuation and B is line phase shift. At the lower frequencies the line is very short and G and Capacitance and then K, can be calculated directly from measurements and line dimsnsions.

12. A clinical thermometer can be inserted deep in the soil. If the test cylinder is too large to fit in the domestic fridge, by leaving the test sample out of doors overnight in winter the effects of temperature can be observed as the sample slowly warms up from freezing. Soil has a high negative temperature coefficient of resistance. Resistance increases as temperature decreases. My garden soil is roughly -2 percent per degree C at 20 degrees C.

13. I have made HF measurements in other shaped containers, usually smaller and plastic, with copper sheets for electrodes. Also in the garden itself between radials and arrays of relatively short rods. Any sort of measurements are more useful than none.

Some people say the only way to deternine soil characteristics is to construct a 1/4-wave vertical antenna, feed it with 50 Kwatt at 500 KHz and measure field strength at 1 mile intervals for 100 miles. And then do some calculations. Don't you believe it!

Ian, correct me if I'm wrong, but I infer that you are biased
toward the "no reflected energy waves" side. That bias could be
based on perceived knowledge.

Seems to me, some people are begging the question. They assume
there is no energy in reflected waves and call what the other
side says, "gobbleygook", even when presented in scientific
terms. I think we all understand the concepts behind net
energy. What is in dispute is the next lower layer of dynamic
energy movement in both directions at the same time during
steady-state.

So would you explain what happens to the reflections of a laser
beam when aimed at a perfect mirror in free space. Offset the
laser beam slightly from normal incidence to start with and
observe the reflections with your naked eye. Then bring the
beam to 90 degree incidence with the mirror. You can no
longer see the reflections but now you can detect the
superposition of the forward and reflected waves through
interference "rings" or loops with an intensity maximum
occuring every half wavelength and an intensity minimum
occuring every half wavelength in between.

Where is the EM wave energy just sloshing around and not
traveling forward and rearward at the speed of light?

==========
Hi Adrian,

Pleased to hear you are now working OK

The correct way to reduce SWR is to adjust the diameter of the
coupling loop.
There's no way to tell which way to adjust the loop except to try it.
It may not be the best setting for ALL bands.
But it IS better to do without the tuner if you can manage it.
Adjust the loop diameter for minimum SWR on your favourite band and it
will also be fairly close on the other bands.

It will be easier to change the diameter of the coupling loop now that
it is just a simple length of wire.

Now that you can hear some noise, the correct way to set the loop and
receiver both to the same frequency is to VERY SLOWLY, vary the loop
tuning capacitor for maximum noise in the receiver.

I am trying very hard not to be biased about the actual problem -
but I am very much against your methods of debate.

Why should anyone consent to follow you into the realms of optics and laser physics, merely because that's where you want to go? Stand your ground right here on the log, Cecil, and talk strictly and exclusively about RF transmission lines.

It might be. But the extra complication of powering an amplifier would bring another load of things to worry about. Simplicity is a wonderful thing.

By far the best way of improving performanc and reducing possible measuring errors, is to increase size of loop relative to length of feedline. Doubling dimensions would make a world of difference.

I suppose he had a good reason for choosing a 1/2-metre square loop.

Hi Reg,

You've presented a very interesting way of measuring soil characteristics. When I return to Florida in November I'm going to use your method of measuring the soil underneath the dipole whose impedances I measured over the frequency range 14 to 15 MHz at various heights above ground, including one set of measurements with the dipole lying on the ground.

One of the reasons I offered to distribute the data from my measurements is to see whether anyone can deduce any soil characteristics from the changes in impedance with height. The changes are significant. For example, the terminal impedance with the dipole on the ground runs from 470 + j250 at 14 MHz to 570 + j132 at 15 MHz. The inductive reactance doesn't become capacitive until the dipole is 2 ft off the ground. In addition, except at zero height, the resistance component decreases with height, but for every height the resistance increases with frequency. Do you think any of the soil characteristics could be determined by such data?

Would you like a copy of my data, just fer the helovit?

>Any sort of measurements are more useful than none.

I don't see you asking Walt for his data to CONFIRM your method. I
don't see you doing any where near Walt's effort in building a sample
matrix of your own to test against your method to CONFIRM your method.
Validation seems to be an orphan in this discussion.

>Some people say the only way to deternine soil characteristics is to
>construct a 1/4-wave vertical antenna, feed it with 50 Kwatt at 500

Bosh! Some people indeed. Your biology instruction in the British
school system apparently didn't teach you the difference between
people and straw-men.

The veiled suggestion of a result
>10. Using classical transmission line formulae in reverse, the values
> of line conductance G, capacitance C and hence permittivity K of the
>"insulating" material, i.e., the soil, can be calculated.
is representative of an extremely thin veneer, ignoring the bulk that
is so easily found by using the antenna in situ - the method you
dismiss as unbelievable, and what is experienced every day by
absolutely every Amateur on "Earth."

Reg, it was a nicely scripted recipe. It contains well explained
methods. It attends practical issues of measurement. However, it
wholly lacks common sense when you reject what is already observable.
What you offer is minutia of an old wife's tale.

For method, any existing antenna's free-space characteristics is far
better understood and revealed through a model than what you offer.
And that antenna's free space Z characteristics compared against
measured in situ Z performance yield the solution of what contribution
local earth has to offer. Single point measurement of contaminated
soil samples has as little chance of doing the same as trying to

measure the ocean's capacity with a teaspoon.

I was working at a company a few years ago, and they built a capacitor of two plates, about 6" on a side, and 0.25" separation. They measured the thing on a network analyzer, and then packed the dielectric with potting soil. Again measuring the results on the network analyzer they were able to deduce the conductivity and permittivity of the soil. I did not think potting soil was typical, but still an interesting experiment.

Frank

PS, Walt, I would very much like to receive your experimental dipole pdf.

Hi OM,

Certainly, but not for the reason of a general prohibition. Antennas'
characteristics are always influenced by other conductors and
di-electrics in the vicinity. The influence is variable in every
novel situation. Separation of at least a quarter of the largest
wavelength (of the two) is a minimum, but is not a guarantee of
expected performance.

Modeling usually precedes implementation so as to reduce endless
rounds of discovering failure.

Ian, GM3SEK wrote:
"I am trying not to be biased about the actual problem - "

Open minds consider arguments.

Wave velocity = frequency x wavelength

Wave velocity in free space is 186,000 miles per second (300,000 km/sec).

Velocity of disturbances on open wire transmission lines is almost equal to that in free space.

At high radio frequencies, a wavelength may be measured in inches and centimeters. A transmission line containing a discontinuity produces a reflection from the change. As a short distance can produce a phase change of 360 degrees, the incident and reflected waves can combine to produce voltage variations along a short line length. These can be measured using simple instruments with confidence.

Circuit theory works on transmission lines because the proximity of their conductors causes an effect on one conductor to be instantaneously imposed on the other.

A transmission line cannot be analyzed as a simple series circuit because current in the wires is not everywhere the same. Volts and amps vary along the line depending upon construction, length. and load placed on the line.

The line`s resistance, inductance, conductance, and capacitance are distributed and accumulate with its length. In a wave in either direction on the line, the volts and amps at any point on the line conform to Zo but also depend on summation of the incident and reflected waves at that point. Current in the linee is not independent of the voltage.

A transmission line of any length terminated with an impedance equal to its Zo has an input impedance of Zo.

Distribution of volts and amps on lines terminated with loads other than Zo has been demonstrated countless times and is well understood. Directional couplers are capable of separating forward and reverse directions on a line, and are also well known, understood and have proved useful. The Bird wattmeter uses a directional coupler, works as advertised, and may be inserted anywhere in a 50-ohm coax line.

Best regards, Richard Harrison, KB5WZI

I have done some more calculations on a square loop fed at the corner. I agree with your results of input impedance. NEC 2 shows Zin at 0.388 + j109. The radiation efficiency of such a loop is 2.88%. I have made a very careful analysis of the currents in the loop when in the presence of a know E field. The current appears to vary in a sinusoidal manner around the loop, with very slight discontinuities at the corners. I assume the variation in current is due to the fact that the induced current is different on those conductors normal to the dipole axis.

Using the RMS current through the 50 ohm load resistor at the corner, and more careful calculations, I obtain an antenna factor of 60 dB, or 24 dB more than your findings. It will be interesting to find why we have such a large difference.

Regards,

Frank

I understand that the CISPR 16-1 QP detector and 9KHz bandwidth are
rooted in a series of subjective listening tests done somewhere around
the 1930s.

(cue storyteller here...)

Firstly, the bandwidth survives, and you are right that it is embedded
in all sorts of EM standards.

I understand that part of the tests I referred to was to discover a
instrument response that fitted well with subjective assessment of the
impact of interference (I presume on an AM broadcast transmission).

I think EMC measurement equipment often contains some of Average, RMS,
QP and Peak detectors.

I have seen several recent reports on BPL radiation that have not used
the QP detector and the reasons have IIRC been that on a scan in xyz
planes over a wide range of frequencies, the EMC receiver is too slow
using the QP detectors.

Ed Hare suggests that the AGC on a receiver acts similarly to the QP
detector, and he is probably right. So the effect being that in an
impulse noise scenario, your receiver will reduce gain roughly in line
with the QP value (rather than say the RMS or the Peak), so it may be a
good measure of gain reduction due to interference. As to interference
with the detection process, the subjective tests to arrive at the QP
detector did not assess impact on digital modulation. It seems to me
that the impact on digital modulation / encoding systems would depend on
the peak value / repetition scenario in concert with the encoding
system's capacity for error detection / correction, but that is just me
thinking aloud.

Measurement bandwidth and extrapolation / interpolation is an issue, and possibly a bigger one than the detector response. Again there is a disconnect between 9KHz MBW (below 30MHz) for the standards and the 2KHz wide receivers in use for SSB. In my opinion, there is no better way to demonstrate the impact of interference in a 2KHz wide receiver than to measure it on a 2KHz wide receiver, so I suggest that (for us amateurs) there may be value in measuring both where possible.

I have a paper showing measurements of soil conductivity made by the accepted method of using a buried open wire line, which sounds similar to your method. The authors found that the conductivity varies considerably with frequency. Have your measurements shown this also?

Years ago someone invented something to place on the tops of antennas
that improved their signals considerably. The military allegedly
purchased many of these. They looked like a ball with a tear-drop
shape where the small pointed end fit over the end of the antenna.

Is this that same device or something along it's principal?

thanks

Source record: 74671

Although knowledge of surface ground conductivity and dielectric constant is much better than nothing, unfortunately it's still not enough to get truly accurate results from modeling or calculation. Most grounds are stratified, as anyone can discover by digging a few feet down, with layers which can be vastly different. The skin depth at 3.5 MHz in average soil is 16 feet, and at 7 MHz and above about 13 feet(*), which means that significant current flows to depths several times these values. To make an accurate representation of the ground would require knowledge of the ground characteristics to several tens of feet.

Fortunately, horizontally polarized antennas are quite insensitive to ground characteristics except at high elevation angles. So for amateur purposes, it's of interest mostly for vertical antennas and NVIS operation with horizontal antennas.

To accurately predict the field strength for vertically polarized antennas, you would need to know ground characteristics typically for a few hundred feet from the antenna (depending on the height and current distribution on the antenna and the elevation angle of interest) -- the distance at which the field from the antenna strikes the ground and reflects to interfere with the direct field. This is admittedly a simplification of what really happens, but the distance where the effects occur is approximately right. You also need to know the ground characteristics in the close vicinity of the antenna to evaluate the efficiency of an antenna having a radial system. Besides the problems of stratified ground, many of us live in an urban environment where buried utilities, pipes, reinforcing bar, and houses are likely to be within the radius of interest.

Finally, even if you had exact information about each layer of a stratified ground, I don't know of any readily available program which can make use of that information. NEC based programs like EZNEC can accommodate only a single ground characteristic, and assume that the ground is homogeneous to an infinite depth. I'm not convinced that there's any single value which can be substituted for a stratified ground which will behave like the stratified ground. This is the weakest point of currently available modeling programs. But even if they could model stratified ground, you'd have to know values for each ground layer.

The method used in broadcasting, where the skin depth is on the order of 25 feet(*), of measuring the attenuation of a ground wave signal over a lengthy path is a much more accurate way of determing overall path loss than simple measurement of surface ground characteristics, since it automatically takes into account all the factors I've mentioned.

Again, knowledge of surface ground characteristics is better than nothing, but don't be fooled into thinking that it gives you real information about the ground in which the RF current flows. Had Brown, Lewis, and Epstein measured the surface ground conductivity, it wouldn't have helped us much.

(*) You might notice that the skin depths don't follow the familiar rule of decreasing as the square root of frequency. That's because the familiar rule is valid only for good conductors. Average Earth acts like a good conductor below about 7 MHz, but above that it's more like a dielectric, where the skin depth becomes independent of frequency. Consequently it's not less than 12 - 13 feet at any frequency for average soil.

I haven't looked into this carefully, but one person I know who was very involved in NVIS operation (where ground characteristics are important) tried it some years ago. He concluded that it wasn't possible to set the antenna height and make measurements with sufficient accuracy to infer the ground characteristics with any confidence.

Hi Torsten,

Another attractive solution of one datum trying to solve a multivariate problem.

On review of the material offered at this link above, I find that its "Figure 2, widely used graph of conductivity versus frequency for various soils" is in brutal conflict with other published material. The inscription of "transition frequency" reveals such examples that are off from the data inflections by orders of magnitude. Further, there is no citation for where this figure was lifted (and there is evidence of doctoring, if only to erase the original figure number).

The data in "Table 1, 18" monoprobe, Co = 7.41 pF. On my antenna hill with an AEA-CIA analyzer" also reveals a curious condition that is nearly equal to swamp-like conditions in its Q evaluations, and yet showing almost no frequency variation nearly equal to desert like soil.

The graph, "Figure 10, Comparison of Er between two sites" reveals that the Hill site has a soil condition equal to Fresh Water at 1 MHz. It then plunges to a "Very Wet Soil" condition at 8 MHz (curious thing about this, is that earlier data did not show any frequency variation in Q). The Rose Garden site, again, showed very swamp like conditions. This is a very exceptional region of the country, to say the least. I've seen only one example in fiction: Dilbert's visits to Elbonia where every one lives in waist deep mud.

In graph, "Figure 11, soil conductivity with and without grass cover using an 18" monoprobe," is presented data that is inverse relationship to published data. But this, too, is (in)consistent with other material presented at the link provided.

This goes on and on - to the neglect of confirmation against the numerous references cited (without corresponding discussion nor tie-in).

There is a wealth of data and information, but given it does not agree with other published data, it appears to suffer from a poverty of correlation. The simple numbers revealed as conductivity, di-electric constants and the Q relationships; if used as sanity checks, says that precision and accuracy in measurements does not redeem this analysis.

Something is very seriously in error: either my reading, or the material offered.

Understood, Roy, but was this person saying that with just one height it wouldn't give sufficient accuracy, or is he saying that with impedance knowledge at many different heights there would still be no determination of any of the ground characteristics?

Would you not like to see my data before concluding it couldn't reveal any ground characteristics.?

Hi Walt,

And per my several critiques into this matter, all such broad
proclamations lack the fundamental of drawing a validation through
correlating work in the subject. Let's examine the one point offered:
>> He concluded that it wasn't possible to
>> set the antenna height and make measurements with sufficient accuracy to
>> infer the ground characteristics with any confidence.
This, of course, presumes that this source has any actual
authoritative data. Something that is prohibitively beyond the scope
of an individual to determine (when it is already rejected through
correlations of antenna characteristics and measurements) in the first
place suggests there is none.

Roy has already pointed out the futility of a piece-wise measurement
throughout the bulk of earth soaked by RF to its skin depth. I have
pointed out that these several treatments offered only go to the thin
veneer of soil. Some conclusions drawn were preposterous on the face
of the data offered. Further, to suggest the four lead measurement be
stretched to employing wavelength sized leads is fraught with error
through the denial of those leads becoming what every Amateur already
has, an antenna.

Reg has dismissed the use of an antenna to measure the earth's
contribution of loss, or to distinguish its characteristics by
perturbing the known characteristic of an antenna. Such dismissal is
not an argument - it is a conceit.

Walt, your data is comprehensive enough to build a soil model for the
band you studied. I seriously doubt anyone could challenge your
results if they were internally consistent.

Walter,

What people want to know is how soil constants change with frequency.

Measurements at one frequency will tell you nothing about that.

Yes please, send me a copy of your test results. But I can't
guarantee receiving anything attached to an e-mail. My computer is
playing games. Can you send it AS an e-mail.

Reg.

Do we need to go into the wave reflection model in detail? The Bird wattmeter accepts the wave reflection model as scientific fact as do most of my reference books. Given the wave reflection model and a 50 ohm environment, the Bird wattmeter reads forward and reflected power, i.e. the number of joules passing a point on the 50 ohm transmission line in each direction. The Bird wattmeter assumes: Forward V is in phase with forward I. Reflected V is in phase with reflected I.
Vfor*Ifor = Pfor Vref*Iref = Pref
Vfor/Ifor = 50 ohms, Vref/Iref = 50 ohms.
Vfor^2/50 = forward power, Vref^2/50 = reflected power
Ifor^2*50 = forward power, Iref^2*50 = reflected power
All this is in any good textbook covering the wave reflection model and has been accepted as fact by RF engineers for the better part of a century.

I see nobody picked up my deliberate mistake! Using Terman's simplified formulas on pp 813, and 814, I get identical parameters of induced voltage, and antenna factor. I completely agree with the results of the Mathcad file, although have not gone through the more intricate equation development yet.

Using NEC 2 I found out, the hard way, that maximum pick-up takes place off the ends of the loop. Given these constraints: With a field strength of 5.5 V/m, the voltage across the 50 Ohm resistor is 0.091 V RMS, or an antenna factor of 35.1 dB. Within 0.4 dB of Owen's results.

Interesting exercise, and I actually learned something.

73,

Frank

Actally, on HF, you will never have an antenna that will give you the boost
of an amplifier. I can think of any number of occasions when I was part of a
DX pileup with 100W; finally threw in the towel and fired up the amp. Guy

would come back to me on the first or second call.

I interpreted what he said as meaning that he looked into the method and
determined it wasn't practical. Surely he thought of making numerous
measurements. He's a very capable engineer, so I took what he said at
face value. On the other hand, I don't think he's highly skilled in
making precision antenna measurements, so he might have assumed that a
level of accuracy wasn't achievable which in fact might be.

You might spend a little while with EZNEC looking at how much a change
in ground conductivity or permittivity changes the antenna input Z at
various heights, and how much the height changes the Z with a given set
of ground characteristics. Then consider whether you'd be able to set
the height and make the impedance measurements accurately enough to
infer the ground characteristics with any degree of confidence.

> Would you not like to see my data before concluding it couldn't reveal any
> ground characteristics.?

I'd like to see your data, but it wouldn't be enough information to
conclude whether the method would be practical or not.

That is great Frank, I like it because it agrees of course, but if its a valid model, that is even better.

My model was much simpler in just trying to establish the Z of the loop, I didn't do what you have done and irradiated the loop, well done. My only residual concern is whether your receive loop was far enough from the exciter to be truly operating under free space conditions. I suppose if you double the distance and get nearly identical results, that would be sufficient confirmation.

Two questions:
1. can I have a look at your model;
2. would you permit me to publish it (with attribution) on a web page that I am drafting on the antenna design for BPL interference and other interference measurement purposes.

BTW, although the gain is really low, I have also used it effectively for getting bearings on interference from afar (though, DFing HF signals is problematic, especially at high path angles).

Life is fun, isn't it.

There is more to ham radio that "logging-in" to content-free nets, talking about what is on the menu for dinner. Indeed, I suspect that more "real" ham radio takes place off-air than on-air.

It would be interesting to recreate the measurements at other locations. My location has 500 feet of sand below me. It would be a great improvement just to have poor soil.

Except that the "sloshing energy" comment doesn't have the energy sloshing from the load to the match point and back at the speed of light. As I understand the concept of "sloshing energy" it is sloshing back and forth rather locally between the inductance and the capacitance.

Hi All,

Reg asked if I could send my data as an email, so I converted the file to text format to be able to present the data in full here in this msg.

I checked to see that the tabular format remained intact, and it did in Outlook Express, so here it is. I hope the tabular format will remain intact in your browsers. Be sure to give your screen maximum width. If it doesn't, let me know and I'll resend in PDF format.

I'd like to hear your comments.

Walt, W2DU

Dipole Terminal Impedance Data Obtained From Measurements at Various Heights Above Ground in the Frequency Range from 14.0 to 15.0 MHz. Measurements Made be W2DU at the W2DU site in DeLand, Florida.

Reg, to answer your request to put my data in a format useable in an email without attaching a file, I found a way to convert the data to a text file. Consequently, I uploaded the entire data file in the preceding thread, Antenna Impedance Measurements. Please look for it there.

Walt

Reg, I goofed. The antenna impedance data in text format went into this thread by mistake instead of into the Antenna Measurements thread.

Unfortunately, the tabular integrity is not as good as with the PDF file. I hope you can decipher it.

I have modified my EZNEC model to irrradiate the loop from an exciter dipole at some distance. I have tried it with the exciter at 100m and 200m distance, I get AF=35.69 and 35.72 dB respectively (against 36.1 from the Mathcad model). I note that if you report on the so called near field values too close to the loop, the results are effected by the loop.

I note that the Matchcad model estimates the inductance slightly higher than EzNEC, and others have suggested to me that the Lw term in the Matchcad model is a double up, that the Ll term fully accounts for the inductance of the loop. Removal of the Lw term results in an AF of 35.8dB, which is closer to the EzNEC prediction.

Has anyone views of whether Lw should not be included?

The currents in my model vary slightly, here is the current report:

Frequency = 7.1 MHz

Walter Maxwell, W2DU wrote:
"Do you think any soil characteristics could be determined by such data?"

Kraus has an interesting figure, No. 11-20 on page 305 of his 1950 edition of "Antennas". It is the feedpoint resistance versus height in wavelengths over perfect ground (a copper sheet?) of a resonant 1/2-wave dipole.

It varies from zero ohms at zero height to a maximum of about 100 ohms at 0.35 wavelength above ground. The resistance settles down to just above 70 ohms at infinite height (free space radiation resistance value).

Clean dry sand may be a very good insulator. If it were deep enough, a dipole lain on it might have a feedpoint of about 70 ohme. Better soil conductivity might shift the drivepoint of the dipole to a lower resistance as the Kraus figure indicates for perfect ground next to the dipole.

Several measurements at slightly different locations and times may need to be made and averaged for reliable results. The curve in Fig. 11-20 oscillates around the free space radiation resistance so that at some altitudes feedpoint resistance goes down as altitude increases. One would need to know which part of the curve the measured resistance fell upon.

Walt may be on to something with his method for determining earth constants. There are so many broadcast stations in the USA that soil conductivity has been already determined in nearly all areas. For unknown areas, one could lay out radial paths from existing stations and measure feild strengths along the radial at several places and see how much more attenuation there is versus the "unattenuated" values expected and determine average ground conductivity by the loss added by the ground.

Best regards, Richard Harrison, KB5WZI

Depends on your objective. For NVIS operation with a horizontal antenna, where you need the reflection, that's probably true. But for a vertical or for DX with a horizontal antenna, you're better off with the sand. Perfect ground has no loss; free space has no loss. There's an intermediate quality of ground at which the loss is maximum at a given frequency. Unfortunately, this happens to be in the range of ordinary ground characteristics in the HF range. Your ground should be very low loss. And your pattern should resemble free space, with a very strong field at very low radiation angles.

1582. Re: Receiving loop antenna design

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-21 06:50:33 UTC
From: Owen <none@no.where>
Message-ID: <ZMOte.24771$F7.11558@news-server.bigpond.net.au>
Source record: 74548

I have written a deck for NEC2 which uses and incident plane wave as the excitation scenario.

The deck:

```
CMSmall square untuned loop
CMEXTENDED THIN WIRE KERNEL USED
CM1. FREE SPACE
CE2. Plane wave excitation
GW 1 9 -0.25 0 1 -0.25 0 1.5 .0007
GW 2 9 -0.25 0 1.5 +0.25 0 1.5 .0007
GW 3 9 +0.25 0 1.5 +0.25 0 1 .0007
GW 4 9 +0.25 0 1 -0.25 0 1 .0007
GE 1
EK
FR 0 1 0 0 7.1
EX 1 1 1 0 90 0 0 0 0 0
LD 4 1 1 1 50 0
GN -1
XQ
EN
```

I get an antenna factor of 35.8dB/m by multiplying the current in wire 1, seg 1 (the location of the 50 ohm load) by 50 ohms, and taking -20*log of that voltage.

Owen

PS: This won't work if you are working with one of the original column formatted Fortran inputs, but it does work with nec2++ (http://www.si-list.org/NEC_Archives/swindex.html)

Ah Punchinello!

No, I am not clever at all. You can chalk that one up to charity.

You are certainly entitled to the last say -
"put some dirt in it and say Amen."
(John Wayne in "Red River" an example of high conductance earth of the
Texas panhandle country.)

Hi Walt,

Thanx big time for this work of dedication. I have other projects to
attend to, but I am sure looking forward to close examination of this
trove of data by hunkering down with Mathcad and casting up some
charts. Hope to do that within the week if not sooner.

1587. Hy-Tower on 160

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-21 11:09:02 UTC
From: Larry N8KU <listacct@longwire.com>
Message-ID: <tr2dnRIQQNqFaCrfRVn-sg@bright.net>
Source record: 74553

Hi guys.

I have a Hy-Tower, with the 160m add-on inverted-L. It has never loaded up well, even when it was working properly, the best I could get was 3:1 at 1840 KHz.

Now, it has gotten worse, (water in the trap?) and I am re-thinking the situation. Is there any reason why I shouldn't just forget the trap, and attach the inverted-L wire at the base, and then just use an insulator near the top to hold it up?

This would be essentially a second antenna, a few inches from the first. It may cause a change in the loading on 80 or 40, but nothing that my tuner can't handle.

Ideas? Suggestions?

Larry DiGioia N8KU

Do "good college E&M courses" cover the conservation of
energy principle applied to canceled EM waves? That topic
seems to be a black hole in the education of the average
electrical engineer.

Fair criticism. It reflects tiring of posting before its conclusion.

The Bird wattmeter`s firectional coupler distinguishes between incident and reflected waves by their singular difference. Upon reflection of a wave, either the voltage or the current it generates is reversed in phase, but not both.

Bird takes equal samples of voltage and current from the wave.. When there has been a reflection, the samples have opposite polarity and cancel. When there has been no reflection the samples from that direction of travel are in-phase and the sample total is double the contribution of either sample.

To determine reverse power flow, the polarity of one of the samples is reversed.

You don`t need to know how it works to use it and Bird never advertised how simple it is as far as I know.

Bird assumes the wave reflection model is valid, i.e.
Vsample proportional to Vtotal = vector sum of (Vfor+Vref)
Isample proportional to Itotal = vector sum of (Ifor+Iref)
Vfor in phase with Ifor, RMS Vfor/Ifor = 50 ohms, Vfor*Ifor=Pfor
Vref 180 deg out of phase with Iref, RMS Vref/Iref = 50 ohms
Vref*Iref=Pref

These assumptions are valid for a 50 ohm feedline of reasonable
length.

These assumptions are obviously not valid if no feedline exists
or if Z0 is not 50 ohms, which is, as I infer, Ian's objection.

> Best regards, Richard Harrison, KB5WZI

Richard, your indication that the dipole input resistance of 100 ohms at 0.35 wavelength above ground is interesting, in that if you look at Kraus' graph of mutual impedance of parallel side-by-side radiators in his Fig 10-12, Page 266, you can see the reason for this.

At this height above ground the the dipole is spaced 0.7 wavelengths from its image in the perfect ground plane. The mutual resistance at this spacing is -24.8 ohms, as shown in Fig 10-12 and in Table 10-1 on Page 267. Table 10-1 also shows the self resistance minus the mutual resistance at this spacing to be 97.9 ohms. There is the approximate 100 ohms shown in the graph of Fig 11-20. Note that 97.9 - 24.8 = 73.1 ohms, the nominal resistance of a thin half-wave dipole in space.

Of course this data relates only to the condition of perfect ground, with total reflection and no attenuation. I would hope that the delta R and delta X values vs height taken from my measured data might shed some light on the ground conductivity and permittivity under my antenna. My soil is very sandy. Knowing that, the delta values might show some tendency to verify that condition.

Hi Walt,

Even on simple examination, it proves useful. It obviously exhibits
the wire wavelength altering effect of the proximity of earth. This
is something Reg has harped on for years and which he curiously
rejects as being incapable of demonstration in just such as your data.

Perhaps this curious twist is explainable. There seems to be a new
vogue of posting errant hypothesis these days so the authors can prove
themselves wrong. I've seen three such admissions in just the last
week.

1600. Bugcatcher antennas/messin' in the shop

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-21 16:00:08 UTC
From: Jerry <joxendi@bellsouth.net>
Message-ID: <FNWte.152107$J25.111126@bignews6.bellsouth.net>
Source record: 74565

While I build the Carolina Cyclone screwdriver antennas (hobby as well as a bit of profit), I recently realized that there is still a little market for the tap-tuned and/or single band bugcatcher antennas. Some of us don't want or need a screwdriver antenna, perhaps, aren't willing to spend the money for screwdrivers, or only hang out on one or two--maybe 3--frequencies. So I started building
the Cyclone Juniors---Models 8010 and 4010, the numbers obviously being the bands they cover. They are semi-open coil forms made of hard, black nylon, hollowed inside for weight reduction with open grooves the length of the coil to allow clips to be placed at various points on the coil (similar to the old Texas Bugcatcher) for attaching wander leads. These antennas are to be center-loaded with a 2-3 foot mast and a 5-6 foot whip. An impedance coil is included for matching. If someone wants a longer mast (these MUST be secured just like a screwdriver about 1/2 way up the mast due to wind loading), you may specify such up to 6' at no extra charge. Prices are reasonable, too, at $89.95 for the 4010 and $109.95 for the 8010. Includes wander leads and alligator clips for tapping coils.

Also, if you don't like the wander lead (I, too, think they are ugly) hanging out there in the breeze, you can order the coils with banana-style plugs on the bottom of the coil.
This is so you can pre-tune your coil for up to 8 bands/frequencies by "plugging in" to a pre-tuned tap on the coil. This eliminates the ugly wander lead and also allows one to install a weather cover to keep out rain and ice. Either sked 20 PVC is offered or 1/8" wall Lexan clear. Both make for an attractive installation. This option is $25.00.

Again, I am just a retired fella tinkering around in my shop. Antennas are one of my hobbies, and I just thought it might be of interest to others. If anyone is interested in the Cyclone Junior, just email or go thru the screwdriver
website at QSL. The bugcatchers have not appeared on any website yet, but it there is interest in these antennas, they will.

Hope they got it right this time.

My dictionary says: "conjugate - Either of a pair of complex numbers that are mutually related in that their real parts are identical and the imaginary part of one is the negative of the imaginary part of the other.

We find maximum power transfer requires equal resistances in source and load. Also reactance, if any, be tuned out of the circuit. This is a conjugate match, such that source and load are conjugates by the dictionary definition.

Many texts go into detail. I like the story of conjugates given in "Transmission Lines, Antennas, and Wave Guides", If it were at hand, I would quote from it. Found it. See page 43. The authors are King, Mimno, and Wing.

I accept that, but cannot reconcile page and figure numbers. I have only the 1950 and 2003 editions of "Antennas". They are prticeless to me though I`m not as familiar with them as I am with Terman.

I suggested determining ground resistance by the attenuation it adds to the ground wave. I neglected to say that the time to do so would be when sky wave propagation was small to none. Midday when using medium wave signals for signal strength measurements unless the measurement sites were close enough to the transmitter to make sky wave unimportant. I used to make medium wave broadcast station monitoring point field strength measurements within a few miles from the station, daytime, nighttime, or anytime because at this short range there is no chance of sky wave interference. You would be much more considerate of the time of day 200 miles from the station. If HF signal attenuation versus distance from the transmitter is used to determine earth resistance, for practical purposes ground wave propagation is nearly negligible, especially at the high end of the HF spectrum. I believe B, L, and E. used 3 MHz which produces some ground wave.

Best regards, Richard Harrison, KB5WZI

Anecdotally, I have noticed, I have no problem working Europe, ZS, VK, and ZL on 75 running 90 watts. I am typically 5-9 or better in to Great Britain. My antenna is 38 feet in the center and 20 feet on both ends. Actually I have two 132 foot dipoles that are orientated 90 degrees from each other. They share a common relay box for switching in additional ladderline. That is the input to the relay box is selected by a separate relay. The unused antenna is grounded. I have tried it both grounded and ungrounded and it "seems" to be better when the unused antenna is grounded.

My next set of relays will tie them both together as a big capacity hat on 160. Have not got around to doing it yet.

I can push a 10 foot ground rod into the ground by hand. If I don't wet it down, I can rotate it by hand when it is 9.75 feet in the ground. If a rabbit gets in the garden, one is in dire straits trying to find a rock to throw at it.

A sand pit down the road from me is over 200 feet deep and they have not hit anything other than sand in over 20 years of digging.

Sure. If you'd kept to the original very steady pace, you'd still be
writing... which is not what we do in newsgroups.

>The Bird wattmeter`s firectional coupler distinguishes between incident
>and reflected waves by their singular difference. Upon reflection of a
>wave, either the voltage or the current it generates is reversed in
>phase, but not both.
>
Yup.

If I can fill this out a little...

>Bird takes equal samples of voltage and current from the wave..

This is done by the pickup loop, which is both inductively and
capacitively coupled to the center line. The capacitive coupling gives
the voltage sample, while the inductive coupling gives the current
sample.

The current sample runs through a resistor, which develops a voltage
that is made exactly equal to the direct voltage sample. So now we have
two RF voltages appearing in series. In the forward direction, the thing
is built so that these voltages add in phase.

When you rotate the slug by 180deg, the phase of the current sample
reverses but the phase of the voltage sample does not, so now the two
voltages subtract. If the instrument is terminated in its design
impedance of 50 ohms, the voltages (should) cancel exactly, so the meter
reading falls back to zero. There's a small capacitive tab on the pickup
loop that allows the meter reading to be nulled exactly.

>When
>there has been a reflection, the samples have opposite polarity and
>cancel. When there has been no reflection the samples from that
>direction of travel are in-phase and the sample total is double the
>contribution of either sample.
>
Er, yes, pretty much...

>To determine reverse power flow, the polarity of one of the samples is
>reversed.
>
And here you've made that big leap again. Where did "power" come from?
Nothing in what you or I have said above explains how come the meter can
read "Watts".

That's because it doesn't actually measure watts. It has been calibrated
in watts under certain specific test conditions, using a different kind
of wattmeter that actually does measure watts.

>You don`t need to know how it works to use it

No, you don't. But if you choose to use it as "evidence" in a discussion
about waves and reflections, then you do need to know how it works.

>and Bird never advertised
>how simple it is as far as I know.

Possibly because it isn't actually as simple as it looks.

Hi Richard,

Your mentioning Mathcad, (I have 2000i ed.) made me think of using Excel to produce some graphs of the data, however, there are two other projects that must come first. I have used Mathcad only to solve problems using the equations one can build there, and have not explored the graphing possibilities. With both Excel and Mathcad available do you think I should spend the time learning graphics with Mathcad, or stick with Excel which I already know how to use?

Walt, would it be possible for somebody to go to B.L & E's original site and measure the soil charateristics which they completely forgot all about. Presumably, they were not aware that the type of soil had any effect on their measurments. At what time of the year did they conduct their famous experiments?

Pity we shall have to wait till November for you to re-visit Florida. In view of the high temperature coefficient of soil resistivity and probability on permittivity, don't forget to take a thermometer.

What was the soil temperature when you made your HF measurements versus height? Soil temperate discrepancies might be of greater order and swamp the effects of considerable changes in antenna height.

But I suggest we are more interested in change of antenna impedance versus height above ground than we are in apparent change in soil characteristics versus frequency.

I too am afflicted with Alzheimer's. I forget what I said at the
beginning of a vocal sentence before I get to the end. Also I have
recently had a very minor stroke which has affected the small and next
fingers of my left hand. This has slowed down my keyboard dexterity.

But it's quite normal for my time of life and it doesn't worry me.
Least of all does KB7QHC's lying slander worry me.

It is futile to accept Mathcad or any other program as being the Bible
unless one is sure that the underlying reasoning, by the user, is
correct.

Validity of the results are dependent solely on the user, plus the
possible uncertainty of program bugs.

Well, perhaps the validity of the model, which leads me to...

Reg, I mentioned in an earlier post that I was concerned about the estimate of the loop inductance. It was suggested to me that the Lw term that I included because it was in a prof's lecture notes was a double up, and that the La term sufficiently estimates the inducance of the loop.

Searching the net suggests that there is some degree of black magic or black art in estimating inductance of such things, and that Grover and Terman had a view on it, but the formula I used seems to be commonly used by online calculators and perhaps a more modern view.

Can you (or others) throw any light on the most appropriate formula for estimation of the inductance of a square loop of about the size in the model (0.5m sides, ~2mm dia copper wire).

I do recall that you said what I have done is too complicated and it can be done with a hand calculator... but I would like to find an expression for the inductance of the loop that will be accepted generally as the best estimate withing the other constraints of the model and construction.

All constructive help appreciated.

Owen

It operated a lot better than "Dr." (not so) Slick does.

He makes a comment that no one here builds amps. I present evidence to the contrary and this is the best he can do.

What a loser.

I worked about 30 states on two-meters from the depths of AZ using that amp. The present amp has participated in working all continents (WAC) on two-meters.

Hi, Owen -

I don't know if the following posts will be of any help at all.

Subjects:
Wheeler's 1982 formulas verified
Wheeler's 1982 formulas verified - Wheeler.gif
Another solenoid inductance calculation - Solenoid.zip

group:
alt.binaries.schematics.electronic

Good luck.

John

Try soldering a female bnc connector on the pcb
then you can attach an antenna at will

Reminds me of the old quote "Fire at Will" - but Will ducked just in time.

==========

None, except that you are nit-picking as usual.

And that B, L & E, all three of them, were floundering about in an amateurish fashion.

Yet it had been well known to others for 35 years that soil conductivity and permittivity had a profound effect on ground wave propagation.

All they had demonstrated was that 113 radials was more than sufficient for MF and low HF broadcast propagation which was what everybody already knew.

And so the rounded-up, Marzipan the Magician, magic number of 120 got stuck in the bibles. A typical American way of going about things. ;o)

Lying slander is a redundancy, isn't it? Just the opposite of sanitary sewer as an oxymoron. I've been enjoying Richard's redundancy and Punchinello's responses immensely.

But I'm sure that won't stop you from your frequent complaints that they "forgot" to measure it. I see you've found other things to criticize, though. . .

, except that you are nit-picking as usual.

Asking what use it would be to measure the surface conductivity (as you suggested) is nit-picking? You have a strange way of evaluating things.

> And that B, L & E, all three of them, were floundering about in an
> amateurish fashion.

Ah, you play the role of armchair quarterback very well. Sure is too bad you didn't think of doing the experiment in 1937 -- I'm sure you would have done it right. All AM broadcast stations would be using precisely 100, not 120 radials, and we'd know the surface ground conductivity of the measurement field (but still wouldn't know what to do with the information). The Reg of '05 would have the warm, satisfied feeling of knowing that another seminal piece of work was done by one of Her Magisty's loyal subjects (or was it His Magisty in '37 -- I forget) instead of the gnawing aggravation he experiences thinking that some American ruffians might actually have done something useful. Life would sure be a lot better today, wouldn't it?

> Yet it had been well known to others for 35 years that soil

Propagation, yes. But nobody had a good handle of the effect of ground systems on antenna efficiency until their experiments.

> All they had demonstrated was that 113 radials was more than
> sufficient for MF and low HF broadcast propagation which was what

You obviously haven't read the paper. It has nothing at all to do with propagation.

> And so the rounded-up, Marzipan the Magician, magic number of 120 got

Boy, it really must hurt deeply to think that some Americans did something that the rest of the world considers to be pioneering. Have some more wine -- it'll dull the pain.

But under no circumstances should you actually stoop to reading the paper you're so fond of criticizing. It would just make you feel worse.

Hi Walt,

The laws, and I imagine the understanding, varies immensely across all borders and jurisdictions. In some places it is slander to reveal the truth, in others to disparage with a lie.

One could imagine the paradox of uttering a lying truth, I suppose. However, given Reg's propensity to slander outrageously, as though it were a prerogative of old age and infirmity, and to wrap me in under the same mantle well before my time (but perhaps not infirmity); this callow youth takes it as no less honour than the tap of the sword on the shoulders by a Queen.

Alternately, lacking any quantitative data, a shortfall that Sir Kelvinator of ice box fame would shudder at, I cannot think Reg's opprobrium is any less part of the act of Punchinello (in other words, indistinguishable from honest labor when such is so mixed with intemperance and reckless fulmination).

Either way, I always enjoy the flourish of his hyperbolic arcs.

"What conclusions could we draw from that information?"

My comment is a little off topic as it is not about measuring soil constants. It is only an opinion that the FCC`s decisions regarding a standard grounding system for medium wave broadcast stations worked out very well. 120 redials each about 1/4-wavelength seems to work well whether soil is good or bad.

In summer or winter, if the ground cracks open from drought or is covered with a foot or more of floodwater, the tower currents and field strengths hardly change at all. Directional patterns are unaffected. Amazing and well done!

Best regards, Richard Harrison, KB5WZI

Fred,
Depends on how long and thick they are. But in general, just
sufficient to meet overall technical and economic requirements with
one or two more for luck.

Design engineers, just to be awkward, are inclined to deliberately
avoid 120. Then they can sit back and have a good laugh when it still
works.

Earlier I said a volume of soil between electrodes behaves as a capacitor in parallel with a resistance.

To conform better to the impedance-frequency response of real soil, a better simulation is obtained with another resistor in series with the capacitor. Better still add a 3rd resistor in series with a second capacitor, both in shunt with R1, C1 and R2.

I have a computer program somewhere which assists in designing a circuit to simulate a given type of soil. But what use such circuits might have is a matter for conjecture.

It is more convenient and practical to work in terms of resistance rather than the scientific term conductivity. Ohm-metres rather than milli-Siemens. When thinking in terms of conductivity I always feel I should be standing on my head.

The resistance measured between opposite faces of a 1-metre cube of the soil is 1000 ohms when the soil has a resistivity of 1000 ohm-meters.

A poor soil is 1000 ohms = 1 milli-S Sea water is 0.22 ohms.

One can visualise a 1 metre cube of the material. The permittivity of the material being the nunber of times the measured capacitance exceeds the calculated capacitance between the electrodes when only air is present. It's about 9 pF.

Are BLE's original papers available on the web? If not, that does represent a substantial problem.

Despite having several derivative references, I must admit to never having seen the originals either. But I do have enough information to judge BLE's work worthy of respect. Pioneers always deserve an extra helping of respect because - unlike everyone else, including all their critics - they didn't have the benefit of perfect hindsight.

On the other hand, that work was done almost three-quarters of a century ago. If we don't know more than the pioneers did, then we have wasted their efforts.

>strengths hardly change at all. Directional patterns are unaffected.
>Amazing and well done!

Well, not exactly amazing, since the FCC deliberately requires the ground to be covered by so many radials that the location and its ground conditions don't matter any more.

That was an administrative policy decision rather than a technical one. From the technical viewpoint, everybody agrees that 120*0.25wl is more than enough to override the local ground conditions under the tower irrelevant.

The real technical question is: how many, and how long, will be "just enough" for "here"? That obviously requires a lot more knowledge and engineering judgement.

Having just taken delivery of two miles of radial wire, the question of "How much is enough?" is starting to become very practical...

> . . .

And for the purpose at hand. We have to keep in mind that the requirements for AM broadcasters are quite different from those of amateurs. A few percent difference in field strength means a few percent difference in a broadcaster's audience size and therefore in advertising income. This income difference is felt year after year, so any change that brings a few percent increase in field strength is worth a fair amount of money for a broadcaster to implement. On the other hand, a difference of 1 dB (more than a 20% change in efficiency or 10% change in field strength) is seldom worthwhile at all for most amateurs.

I'm not sure why the great hangup on how many radials AM broadcasters use. It certainly isn't what most amateurs need.

Source record: 74426

Reg,
Sorry to butt in but I have a loop question.

Presently I have a loop for 20M made from 1/2 inch copper pipe in the attic. I use a large 4500v variable capacitor turned by a small motor. It works very well and is better than my GAP Challenger vertical (31ft) in favored directions. Noise is higher in the attic but I can bring that down with a Timewave ANC-4 noise canceling (by phasing) unit.

My question is about the coupling loop. Everything I had ever seen on the coupling loop was that it had to be an odd construction of coax, i.e. some sort of Faraday shield?? I noticed your comment to Adrian about a simple stiff wire coupling loop.

Is this loop simply shield to one side and center conductor to the other?

Is there a size/diameter ratio of the coupling loop to the main loop?

Is the antenna now more likely to have increased noise due to an "unshielded" coupling loop?

Thanks & regards,
Dick N3HKN

> read "Watts".

Bird assumes the meter is being used in a 50 ohm environment. Bird assumes after the two sample voltages are superposed, that the calibration is accurate to within 5% of full scale. The calibration is done using 50 ohm matched lines.

In a transmission line, the net power transfer is V*I*cos(theta). It can be proven mathematically that, for a transmission line with reflections,

Pnet = V*I*cos(theta) = Vfor*Ifor - Vref*Iref

The Bird sampling circuit allows one to read either (Vfor*Ifor) or (Vref*Iref) by turning the slug. Bird assumes Vfor/Ifor = Vref/Iref = 50 ohms.

than one, rho can be greater than one, rho can be greater than one....

1650. 60 meter ERP

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-22 13:39:15 UTC
From: Buck <iam@this.site>
Message-ID: <t6nib156q2abuogtpde3nubb26vq5mppde@4ax.com>
Source record: 74438

I am trying to calculate how much power I am allowed to run to operate on 60 meters. Here are the two antennas:

1) 80 meter dipole 129 feet long. The antenna is fed with cable TV coax with only the following markings: E83032 F6SSVV (UL) CATV There is no balun on the line. Just the 75 feet of coax from the back of my tuner to the antenna. The tuner is fed with RG-8X-95 coax 3 feet long.

2) Antenna Specialists 75 meter mobile whip antenna. The windings will be removed until it matches on the center 60 meter frequency. The antenna will be mounted on a mag-mount on the top of a Ford Aspire.

I tried modeling the dipole using ARRL-EZNEC. I modified one of their dipoles so I get the extra segments. Here is what I have done so far:

Wires: 1) 0, -64.5,50,-,0,64.5,50,-,14,55
Sources: 1 @ 50%
Loads 0,
Xmission line 0
Ground type: Free Space
Wire Loss: Copper
Units: Feet
Plot Type: Azimuth
Elevation angle: 15
Step size: 1 deg
Ref level: 2.15 (dipole as per ARRL Handbook)
Alt SWR Z0: 75

Here are the results as I read them:
SWR Plot: 5.33 - 5.4 step .005
50 ohms, SWR is 59.8 - 62.6
75 ohms: SWR is 40-41.9

When I view the far field plot, it says at the bottom of the main window, Average gain - .983, = -.07 db Model Contains Loss

With the mininec ground, I get an average gain of .764 = -1.17 db

I haven't accounted for the coax. I tried adding it but the program froze up and I had to start over.

From what I hear, rumor among hams is that mobil antennas can run over 100 watts and still not violate the erp allowed on the band.

I plan to replace that antenna with a 135 foot wire fed with 300 ohm
TV twin lead into my tuner direct.

Can anyone tell me the highest legal power output I can use to operate
on 60 meters with these antennas?

Thank you,
Buck

1651. A Single-Core 4:1 Current Balun

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-22 13:40:26 UTC
From: Chris Trask <christrask@earthlink.net>
Message-ID: <eTdue.7890$jX6.6278@newsread2.news.pas.earthlink.net>
Source record: 74511

In recent days on the QRP-L mailing list, the following remarks were made by Tom Rauch, W8JI regarding the design of 4:1 current baluns:

"...it is impossible to build a 4:1 ratio current balun that uses two 1:1 baluns on a single core."

and:

"It's well established any balun made up of series / parallel transmission lines requires different voltages from the start to finish of each transmission line. "

I have devised and modeled a 4:1 current balun using two 1:1 baluns on a single core, and have tested a fully functional prototype. The design can be built without any core, if so desired. The full disclosure of this design with all theory, references, and test results can be obtained from my web page at:

http://www.home.earthlink.net/~christrask/Trask4to1Balun.pdf

The design proves beyond all reasonable doubt that the above statements to the contrary are, to put it mildly, gravely in error.

The Bird sampling circuit certainly is a magical device if it can
allow one to "read" a power directly. Energy and power are always
calculated quantities. You don't have the math right, Cecil.
Try again.

Well, Ian, the BLE paper reports data allowing one to make that engineering judgement. It's unfortunate that my copy of the paper is in my library in Florida, and I won't be back there until November to scan it for the group. However, I have ordered a copy from the Michigan State U library.

The BLE experiments were conducted to determine what combination of radials would form the best simulation of a perfect ground, i.e., what combination would achieve a field strength closest to the ideal calculated value. One factor they considered is that when the spacing between adjacent wires in a grid structure is 1/20 lambda or less, the effect is that of a continuous reflecting surface. The spacing between radials is not exactly the same as a grid structure, but the effect is similar.

BLE found that the optimum length of the radials in the ground is not related to resonant length as it is with elevated radials. They found that the principal reason for the optimum length concerns the volume containing the significant energy in the electromagnetic fields in the space surrounding the radiator that intersects the ground. They found that at a distance of 0.4 lambda from the radiator the energy in the fields has reduced to the level of diminishing returns, where collecting the currents at a greater distance would yield no significant decrease in loss resistance, and therefore no further increase in field strength. Indeed, the field strength obtained with at least 90 radials 0.4 lambda in length was found to be insignificantly less than that of a perfect ground. This fact was unknown prior to BLE's experiments. I can't remember the exact difference shown in the graph, but it is inconsequential.

With the radials simulating a near-perfect reflecting ground plane the skin depth of the earth beneath the radials is of no consequence, because the RF energy is nearly totally reflected, with only an insignificant amount transmitted through the ground plane. Consequently, the soil conditions directly beneath the ground plane are irrevelant.

However, the soil conditions immediately external to the ground plane are important to the intensity of the ground wave propagation from vertical radiators. The poorer the soil conductivity the greater the loss at low angles of elevation. And as we all know, propagation of the ground wave is frequency

sensitive. Many years ago, using the FCC propagation charts of field strength vs distance for a conductivity of 8, the geographical area covered with a field strenght of 1 mv/meter at 1 mile for a 250 watt station at 550 KHz would require 47 kilowatts at 1500 KHz to cover the same area with the same signal level.

When I receive the requested copy of the BLE paper I'll scan it and publish it for all to see.

Because you're using no balun, the transmission line is part of the antenna and should be included in the model. You'll need to include the entire path to Earth along the outside of the antenna. See "Coaxial Cable, Modeling" in the EZNEC manual for more information, and the DipTL.EZ example file and its associated Antenna Notes file for an example.

> 2) Antenna Specialists 75 meter mobile whip antenna. The windings
> will be removed until it matches on the center 60 meter frequency.
> The antenna will be mounted on a mag-mount on the top of a Ford
> Aspire.

The whip is only part of the radiating antenna, and very possibly the least significant part. The vehicle is the other part. So to find out what the gain of the antenna is requires including the vehicle in the model. A fairly simple wire frame of the outside of the vehicle would probably be adequate, with a couple of wires crossing the top and meeting where the antenna mounts.

The gain is to be referenced to a dipole. The gain of a dipole isn't 2.15 dBi -- that's the gain of a *free space* dipole. To find the gain

of a dipole over ground, model a dipole over ground and use that value for a reference. You'll find that it's more like 6 - 8 dBi. (See example file BYDipole, for instance.)

The primary function of the Average Gain test is to check for numerical errors, not to evaluate antenna gain. See Average Gain in the EZNEC manual for more information. What you need to do is to run a 3D plot, then from it, open the 2D plot. The cursor will be at the point of maximum gain, which you can read in the data box below the 2D plot.

Mininec ground is ok for the dipole model at 50 feet, but you'll need to use High Accuracy ground for the model which includes a vehicle.

> I haven't accounted for the coax.

As I mentioned, you'll need to include the outside of the coax in your dipole model. It otherwise isn't necessary to model the coax.

I tried adding it but the program
> froze up and I had to start over.

Please update your program by going to http://eznec.com/eznec_arrl.htm, where you'll find a link to download the update. If you encounter the problem after updating, please email me.

It would be a magical device if it did that but it doesn't.
The Bird wattmeter is simply an analog calculator. When the
Bird is *calculating* power, it phasor adds/subtracts a sample
voltage proportional to the total current to/from a sample volt
proportional to the total voltage and comes up with a superposed
voltage that is proportional to either forward power or reflected
power depending upon slug position.

In my previous post above I forgot to mention that the displacement currents that enter the ground between the radials don't follow the lossy ground to the center of the radial system. Instead, they quickly diffract to the nearest radial and thus continue toward the center along the radial wire. Consequently, the more radials the shorter distance the diffracted current has to travel to reach the higher conductivity of the wire. The last I knew the FCC requires only 90 radials (every 4°) to comply with the regulations, but many BC antenna engineers use 120 (every 3°).

I discussed this issue in Chapter 5 in both the 1st and 2nd editions of Reflections, with a diagram of the diffraction phenomenon in Fig. 1.

Walt, I'm not Richard but my two cents would be stick with Excel. I have a (now old) version of Mathcad (6.0) and don't use it much. It is much better in handling complex numbers than Excel is tho.

Excel does the math just fine, but the clunky text results are a pain.

Also, I cannot recommend too highly Dan's (AC6LA) Excel based programs. His MultiNEC front end for NEC, EZNEC, 4nec2, Antenna Model, etc. is used all of the time here. For transmission line stuff, including "building" matching networks XLZIZL is also constantly in use at this QTH. Likewise his stand alone TLDetails.exe should be in every ham's tool kit. (I'm a beginning amateur woodworker and just like woodworkers, hams can never have too many tools.)

There is a flaw in your reasoning. In order for somebody to copy an amp, or whatever, somebody else still had to design and write up the original. In many cases, you are here talking to that "somebody else".

Is the publishing of copyrighted papers on the Web generally permitted under fair use rules? The IEEE and other publishers of professional papers charge around $25 for downloaded reprints, and I'd think that would cut into their income. Or does the IEEE specifically permit publishing of their papers on the Web?

It is calibrated in watts assuming that:

Vfor^2/50 = Ifor^2*50 = Vfor*Ifor = forward power

Vref^2/50 = Iref^2*50 = Vref*Iref = reflected power.

This is in accordance with the laws of physics embodied in the wave
reflection model. '50' in the above equations is critical. In any other
environment besides 50 ohms, the assumptions are not valid and the
calibration will be in error.

This interaction among radials has quite a dramatic effect on the
effective ground conductivity. I noticed and reported quite some time
ago that Reg's ground radial program produced answers which disagree
strongly with both BLE and NEC-4 modeling (which agree with each other
reasonably well), and speculated that he didn't account for this
interaction in his program. (I haven't checked since to see if the
program has been modified.) All he says about having to trust the writer
of the program if you don't have access to the source code is true.

Walt,

Your's was a particularly heroic effort and I commend you for it.

I have taken the data you supplied in text form, converted it to comma
separated values (csv) and imported it into XLZIZL where I can use
your measured input values, add the two different transmission lines
that you used and compute the load resistance at the antenna.

I know that you supplied these results, but I find slightly different
answers and I believe the reason is as follows:

I'm guessing that you calibrated your two lines as one. If I'm wrong,
slap me upside the head.

Depending on the exact type, RG58(x) has slightly different Zo values.
RG141 is specified as 50.0. Your Zo of 54 and your phase constant
suggest a Vp of slightly less than .66, which is remarkably close to
specification, but slightly low, considering the ~5% (2', RG141) of
your composite line has Vp ~ 0.7.

This is really getting fussy, but I'm beginning to believe that to
possibly make a determination about ground characteristics based on
antenna Z measurements, the measurements are going to have to be very
precise.

Hi Ian,

To this point there is no controversy, no dispute. Why you should
hedge your assent remains elliptical and probably lies with what you
have to say following.

>That's because it doesn't actually measure watts. It has been calibrated
>in watts under certain specific test conditions, using a different kind
>of wattmeter that actually does measure watts.

All power displays derive from some operations of an implied
mathematical operation and all power displays employ scaling. They
may, each, perform their job through different methods, but all such
methods are still abstractions that require transformation to a common
expression of power. There is nothing distinctive between these
methods (the only separable characteristic) that negates the others
results.

You are going to have to be more explicit about why the Bird's
expression of Power does not yield that characteristic.

Source record: 74433

There must be at least two variable components on every antenna tuner.
This is because every impedance has two components, R and jX.

With a magloop one variable is the loop tuning capacitor. The other
variable is the diameter of the small coupling loop.

It so happens that the setting of the coupling loop diameter does not
change very much from one band to another. Users who never have to
touch it don't realise how lucky they are compared with other types of
tuner which have at least two knobs.

The main loop and coupling loop are like the primary and secondary
windings on an impedance matching transformer. The turns ratio cannot
be changed but the diameter of the coupling loop can be. The greater
its diameter the greater the coupling.

It so happens that for loops of typical dimensions the ratio of the
two loop diameters is approximately 5-to-1. Optimum setting does
change a little from one band to another as can be seen using program
MAGLOOP4 from website below.

The coupling loop is often screened inside a short length of coax line
because the designer saw it done that way in a magazine. Or he just
copied somebody else's without having any reason.

If there's any noise to be picked up it will be 25 times stronger on
the main loop and nobody bothers to screen THAT. What might be picked
up on the very small coupling loop is quite insignificant in
comparison.

And it's much easier to adjust the coupling between the two loops if
one of them is just a self-supporting length of wire no thicker in
principle than the diameter of the coaxial inner conductor.

Instead of reducing its diameter it can be rotated a little or bent
out of the plane of the main loop to have a similar effect. Or
squashed flatter to reduce the area enclosed.

Hi Wes,

You should take care to observe the proviso offered:
"This file does not contain listings for music, movies, or
periodicals."

The practice of many journals is that your material, offered for
publication, is accepted only with the explicit rights of ownership
being transferred to that society. In fact, if you were to cite your
own work without giving a reference to that society's publication,
then you could be held accountable for plagiarism.

The "Open Source" movement has sparked a debate in this regard and
academic authors are being better versed on methods that allow them to
both publish and retain rights.

Thanks for the URL - it looks like it'll come in handy. Unfortunately, the fourth sentence on that page is "This file does not contain listings for music, movies, or periodicals." The BLE paper was published in the _Proceedings of the IRE_, a periodical.

I think the problem is not with the meter. The meter simply tells us, based on several assumptions, how much power might be available to a 50 ohm load if the load were positioned appropriately at the meter location. And, by making some additional correct assumptions, we can accurately infer some things about the absorbtion of power at a remote terminus from the measurements. In my opinion, the only problem is in

drawing incorrect inferences about the behavior of nature based on readings taken from the meter, and from some of the less than fortunate terminology which is associated with the meter readings.

Reg,
Thanks for the confirming information. I will be making a trip to the attic soon. I presently have the 20m loop fed with a Gamma feed which is not too critical but de-mystifying the "plain" loop coupling seems to be the way to go with more variables in geometry. Hams like lots of things to twiddle.

Hi Jim,

This is the legacy left to all measurements being used. None has any absolute authority, nor is any measurement a truth in isolation. Further, without a statement of accuracy or context, no measurement is even valid of anything in particular.

Behavior is demonstrable, or exhibited. It is measured by perception, or by fine grain tools such as meters (which are pathetic in comparison to the eye, ear, or sense of touch for range AND sensitivity). Behavior that is not demonstrable is the enigma of ethics. Would you steal if no one is watching?

I am fully aware of the sub-text of trying to divorce the Bird Wattmeter from the discussion of waves. However to say it does not measure power necessarily pollutes all instrumentation with the same bias of argument. Hence this logic must eventually devolve to no instrument measures power - or waves - or what have you. Rather pointless in the end.

Thank you, Cecil: those key words "calibrated" and "assuming" are
exactly what I wanted to bring out.

>Vfor^2/50 = Ifor^2*50 = Vfor*Ifor = forward power
>
>Vref^2/50 = Iref^2*50 = Vref*Iref = reflected power.
>
>This is in accordance with the laws of physics embodied in the wave
>reflection model. '50' in the above equations is critical. In any other
>environment besides 50 ohms, the assumptions are not valid and the
>calibration will be in error.

So the printing on the Bird scale depends on a calibration using a
different kind of wattmeter - one that measures real RF power delivered
into a 50 ohm load. But beyond that, the calibration for a mismatched
load depends on a large additional helping of theory.

Those are the reasons for the point I'm always wanting to make about the
Bird: it cannot be called in evidence to "prove" anything about forward
and reflected power, because it is entirely dependent on the theories
under debate.

Simply because the theory that converts the Bird's raw readings
(actually rectified RF voltage) into "Watts" on the printed scale is the
very topic that is under discussion.

That means the Bird's readings of "watts" cannot be called as evidence
in the debate. Any argument based on doing so is doomed to be circular.
It *may* still be correct, but that cannot be proved through a circular

argument - you have to find some other way.

>
>Wes

You're right, Wes, I calibrated the composite line as one line. And I agree that if you calibrate them separately a small difference in the results will be obtained. But I believe the difference will be insignificant. Consider this: The nominal Zo of RG58 is 55 ohms and that of RG141 is 50, as you point out. The measured Zo of the composite line is 54 ohms. Now also consider this: The nominal vf for RG58 is 0.659 and for RG141 is 0.695. Thus the difference in the nominal Zo is 10% and the difference in vf is 5.5%, but the length of the short portion is only 5% of the total length. From these small differences I presumed the error would be significant. You didn't say exactly how much difference you

found, or the procedure you used to determine it.

So I made the following calculations from the data where the height is 10 ft at 14.55 MHz:
First transforming the measured input impedance through the 40 ft of RG58, and then transforming the impedance found at the load end of the RG58 through the 2 ft of RG141. The results are as follows:

At the load end of the RG58 and the input to the RG141: 69.41 - j19.19,
At the load end of the RG141: .....79.23 - j3.25.

At the load end of the RG141 using the composite data: 81.21 - j1.25.

The difference in the R values is only 1.98 ohms and in the X values is only 2 ohms. I consider this degree of error insignificant. Would you not agree?

Walt

>I'd like to hear your comments.

Hi Walt,

On first pass, the results are fairly consistent, but with two
exceptions. I am not sure if this is in my translation to file
formats suitable for Mathcad, or if they lie in your process.

Anyway, a general description:

The granularity of 50Khz appears to not be fine enough to find all
peak resonances for the 9 of the 11 within the band. I have rendered
the data into a sequence of 11 curves (one curve for each height) I
call "Q" where that quality factor relates to the ratio of RL to |XL|.
This was merely a survey to glance at all the data at once and to
observe how the Mathcad sheet was taking shape. To this point this
could as easily be accomplished in Excel. Continuing, I noted that
two sets of height data moved retrograde to the general trend.

That general trend revealed a family of peaks that moved up-frequency
as the antenna height was raised. Two of the peaks were out of the
band. One was above the band (the lowest antenna height) and the
second was below the band (the second lowest antenna height). Of
these two, I would suspect that the first, or lowest antenna height,
was a curve rising to peak at the second (anti)resonance - otherwise,
the trend is progressive with two exceptions.

Those exceptions are found in raising the antenna from 8' to 10' and
from 14' to 16'. The peaks in each of these step changes move counter
to the trend: down-frequency when the height is raised. Again, this
may be entirely a transcription error of my own that I need to
investigate further.

The biggest frequency shift comes with (this is a presumption) lifting
the antenna up off the ground to the one foot level. The next biggest
shift comes with the elevation change to the two foot level - and so
on with progressively smaller shifts in frequency shift and
progressively sharpening of the curves as the antenna is hiked higher.

But that makes you a little like the people who believe that man has never walked on the moon. No amount of proof is ever sufficient. And indeed, 1000 years from now, most of what we think we know now will be obsolete.

So all we can do is operate within the laws of physics as we, the human race, understand them to exist at the present time. The debate is underway.

Can photonic wave energy "slosh" around side-to-side at sub-light speeds?

Can the laws of physics embodied in the wave reflection model and conservation of energy/momentum principles really be considered to be "gobblygook" after faithfully serving man during a century of scientific discovery?

Hi Ian,

You have simply invalidated any method to prove the debate. In a
sense, yours is an appeal that nothing can be known and hence nothing
can be proven.

Yes, I know this may be "inflammatory," but I would counter: give me
one method of determining power that does not eventually appeal to
circular definitions.

This, of course, comes at the risk of starting yet another endless
round - pun deliberate.

Very interesting, Richard. I made a cursury check on the retrograde data, and it seems that the trend is in the original measured data. I compared readings of adjacent frequencies for two different heights where the retrograde occurs and found differences in original R values that I can explain only in the possibility of different degrees of soil wetness, because the measurements were not all taken on the same day. The date of each measurement is in the upper left corner of each page. Since the measurements were taken 22 years ago I can't remember whether I logged the rain vs non-rain days, and the original data is in obscure files in Florida. I would not have taken measurements during a rain, but the day after a rain the soil would still have been wetter than the day before the rain. Wetness is the only explanation I can think of for the jerk in the data.

Are your Mathcad graphs in a format suitable for emailing? If so, I'd like to see them.

Hi Chris,

And if I wanted a refinement of what Tom said, does he get the same
chance at dialog as you are seeking?

Too often this turns to one interpreting for Tom (me or you).

Again, you have an issue you wish to present, that's fine, if you want
a debate judged, it needs more than one wrestler.

Strip out the controversy of he-said-she-said and cut to the heart of
what you have to offer. For one, I notice you say you have an
improved BalUn. To me it looks slightly blighted irrespective of what
Tom may have to say (and I certainly don't count him as an authority
on the topic).

Hi All,

This is a life's lesson in the value of context and measurement, as
well as in the discipline of taking notes. Walt's memory suggests a
reason for the perturbation observed in the data, and it is not
unreasonable. I would suggest that there is some (however slight)
likelihood that the correlations may be backwards in that most of the
days followed rain, and these perturbations were on dry days.

Before or after is not the issue. Before or after is a matter of
separability which is more important. With analysis, Walt's
conjecture can be tested against the data and what it reveals about
the impact the ground's proximity had on the antenna.

His data, either way, already supports that ground is measurable
within the data that falls outside of the spread of noise and error.
Even if Walt slipped an instrument reading or injected statistical
noise, he did it so consistently that he was always in error in the
same direction (this is called systematic error). This may impact the
accuracy of the final answer, but it does not impact the thesis'
general conclusion. What is more, even if such mischance occurred
(and I doubt it), it is recoverable with one or several cardinal
measurements to correct the earlier bias.

This round of discussion also reveals that bad data is as good as good
data. Those who discard results and tailor their reports stand a good
chance of not discovering how to fix their problems when they are
shown to be in serious error (which is to say they probably rejected
good results). I pointed this threat out in another thread that
linked to exhaustive ground data that showed hills composed of fresh
water.

"The real technical question is how many, and how long, will be "just enough" for "here"?"

Reminds me of the trailer house designer pulling out reaces until the whole projkect collapses, then rebuilding with only the last brace removed reinstalled.

You don`t need any radials with a horizontal dipole. Broadcasters are launching ground waves to reach a local audience. Amateurs may want ro reach DX with sky waves.
For radials under an earth mounted vertical, there`s no magic number or length. You can add to the count until resistance elimination fades. You can lengthen them until the current at their tips is almost zero. Or, you can just decide how much you will spend on wire. I read that quantity of radials is better than longer radials.

If you want some idea of how conductive soil is, I read that a Variac, ground rods , ammeter and voltmeter is the way to go. Adjust current between the rods to one ampere with the Variac. Resistance between the rods is then the volts between them.

Terman has already supplied Table 22-1 "TYPICAL GROUND CONSTANTS" on page 308 of his 1955 edition for estimating dielectric constant and ground conductivity.

At high frequencies, poor ground conductivity takes eome energy from the reflected wave and the combined direct and reflected wave can`t be a complete cancellation. The direct wave alone is stronger than its combination with an out of phase wave. Ground wave propagetion fades in a short distance at high freqiuencies. So what use does the DXer have for soil conductivity? Isn`t something like Terman`s Table good enough, unless he is considering laying his antenna on or near the soil?

Now, now, boys, be nice. Both of you can be right if you are not
talking about *power* gain. Since you are discussing VSWR, rho can be
greater than one AND the voltage return gain can be greater than one.
The voltage across a resonant circuit depends upon the 'Q' and can
certainly be higher than the applied incident voltage. For that exact
same reason, Vref can be higher than Vfor. It occurs when the load is
the conjugate of Z0 and Z0 is not purely resistive.

What is the technical content here? I don't see a single equation. The moral seems to be "draw no conclusions because they might be incorrect". Whatever happened to the scientific method where a premise is tested against reality?

Yes. As Ian said, it`s been calibrated in watts.

Your spedometer doesn`t measure miles or hours. It has been calibrated in miles or km per hour. Nor, do you need to drive for miles or hours to get a readout.

Certainly. A thermal wattmeter determines the power delivered into a load resistor without making any assumptions about how and why it got there. It only involves measurements of mass, time and temperature rise, and a knowledge of specific heat capacity, so it is completely independent of any assumptions related to RF transmission line theory.

Hi Ian,

So here I will follow your plunge into the rabbit hole.

That thermal wattmeter, and I know a variety of them, each very different from the other, has a scale, just like the Bird. Every meter has scaling circuitry for that scale, just like the Bird. Accurate Thermal wattmeters use AC references and need to transform to DC to drive the scale, just like the Bird. Accurate Thermal wattmeters don't even directly measure mass, time, temperature rise, or specific heat capacity - they infer them by comparison. The measurement is balanced against a simpler substitute - one difference from the Bird that is of no consequence.

Every step of the way, there is a conversion performed to meet the needs of displaying a result, just like the Bird.

Further, the best and most accurate thermal wattmeter is as restricted as a Bird Wattmeter because it (they) too is (are) load specific. A 50 Ohm thermal wattmeter is no more correct on a 75 Ohm line than a Bird Wattmeter. Those same thermal wattmeters all quite deliberately employ the same printed restrictions of operation at a known load without reflections present.

If you are trying to make an appeal to a calorimeter, with thermometer in hand, you are simply exacting the algorithms you must use, compared to the already quantified results that the Bird will offer by the similar math being embedded in the coupling and scaling of a tensioned needle indicator in a magnetic field. Current, field, mass, tension, deflection, time - still in the jumble, they evaluate to power. I've calibrated meter movements, balanced needles, replaced springs, adjusted trim pots, tuned capacitance, replaced resistors - and I have worked and calibrated calorimeters, bolometers, thermistors, thermocouples, barreters, Wollaston wires, diodes, thermopiles, black bodies.... But I've said all this before, and it cannot have escaped your attention. So just what is it about this list of thermal technology that is so decidedly uncircular that it trumps the Bird?

There are any number of ways to measure power, none of them are exclusive, and certainly none can claim to achieve this feat through other than ordinary transformation of physical actions.

John,
Thank you. I went looking through the extensive literature that I have here before sitting down and coming up with this. After it was all modeled, prototyped, and tested I could only wondered why I had not seen something like this earlier.

I've modeled this as ideal transformers, real-world transformers (with losses and parasitics), ideal transmission lines, and lossy transmission lines and it comes out the same, with minor variations of course. I prototyped it with short coaxial cables as I did in order to minimse the parasitics and show that the models and the concept were basically valid.

I'm already catching some flak, but so far it's mostly pointless dribble and obfuscation. You wouldn't believe some of the nonsense that I've been seeing. One person claims that in order to use ferrite properly with coaxial cables to make them appear shorter the ferrite has to be inside the cable between the outer braid and the centre conductor. He was immediately slam-dunked into the kill filter.

Hm. The way I read http://www.copyright.gov/circs/circ1.html#hlc, it has. It looks to me like the original copyright was good for 28 years and for copyrights originally issued in 1937, renewal (if done) was good for another 28. That would put it in the public domain after 1993. I'd sure appreciate comments from someone who's actually familiar with the law -- it's pretty convoluted and I'm not at all confident about my interpretation.

True it gets very complicated, especially when the likes of Disney get
an act through Congress to copyright Mickey Mouse forever.

http://writ.news.findlaw.com/commentary/20020305_sprigman.html

Unfortunately, the Supreme Court was not interested in the
constitutional aspects of this monstrosity and let it stand.

The average citizen can afford to bribe his local officials (democracy
in action), but when it comes to Congress, you need real money.

Publish the paper Walt, the authors are all gone (I think, but you
know better than I) the IRE is gone too; what are they going to do,
come back from the grave and sue you?

FWIW:

1) I doubt this antenna system shows any gain on 60m, most dipoles of this construction wont when operated off resonance. With only 3 db of loss you can safely run 100 watts, Just tune up and go.

2) Antenna Efficiency is so low on HF mobile antennas 100w will not exceed the 50w EIRP limits.

Sounds like the guy works for Fleetwood.

Here's an example of their fine American craftsmanship used on my fifth-wheel trailer. Actually I think they probably have a crew of illegal aliens doing the work but who knows.

http://users.triconet.org/wesandlinda/POS_MallardByFleetwood.jpg

The awning upright kept the sheet from tearing off completely and landing in the middle of I-10 (75 mph limit). Adding insult to injury, I had just increased my insurance deductable before the trip from $200 to $1K to "save money."

The authors didn't own the copyright. (If they did, it would be the property of their heirs if still valid.) But the IRE isn't gone -- it merged with the IEE, back in the '60s as I recall, to become the IEEE. If the copyright is valid, they're its owner. And they might sue.

"Sounds like the guy who works for Fleetwood."

Did not expect to hit a nerve with my story of "Value Engineering". Fleetwood could be called Fleetaluminum after Wes` skin peeled and sailed down I-10 at 75 mph.

When you are making many examples of a product it makes sense to minimize cost if you don`t compromise the product.

A guy in my college class was hired by a car radio manufacturer. He spent most of his first 18 months with the company eliminating a single nut and bolt in a vibrator. His starting salery probably wasn`t much, but I doubt they ever produced enough vibrators to recoup the cost of their design improvement which saved a single fastener. His work must have been akin to that of T.A. Edison finding the right stuff for the filament of an incandescent lamp, finding a thousand things that didn`t work before finding one which did.

>for another 28.

That's the first thing to check - see if there's any record of the
renewal actually taking place in 1964 or 1965. If it didn't, then the
work would have entered the public domain effective 1/1/1966, I believe.

> That would put it in the public domain after 1993.

Here's where I differ with you. The copyright law which went into
effect on 1/1/78 automatically extended the second (renewal) term of
copyright, for works which had been originally copyrighted before 1950
and on which the copyright had been renewed before 1/1/78. The second
(28-year) term was automatically lengthened to 67 years, giving a
total of 95 years of protection.

So: if the work's original 28-year copyright was not renewed, then it
fell into the public domain in 1966.

If the work's original 28-year copyright *was* renewed in its last
ear, then the second 28-year term was effective, was automatically
extended to 67 years by the Copyright Act of 1976, and is still in
force today.

> And the laws of scientific logic, for example: sticking to your initial
> assumptions; and being very careful to avoid circular arguments.

OK, let's take an example. The source (SGCL) is a signal generator with
a circulator and 50 ohm resistor circulator load. The load is a 291.5
ohm resistor.

100W SGCL---Bird---50 ohm lossless coax---291.5 ohm load

We measure 50 watts delivered to the 291.5 ohm load. We measure 50
watts dissipated in the 50 ohm circulator load resistor. The Bird reads
100 watts forward power and 50 watts reflected power. Modulation proves
that the 50 watts absorbed in the circulator resistor has made a round
trip to the 291.5 ohm load and back. Everything obeys the laws of
physics embodied in the wave reflection model and the conservation of
energy/momentum principles. What else is there to know?

All true, but...

Suppose that the IEEE has a staff of lawyers sitting around picking
their collective noses and they get wind of some ham (who actually
knew the authors) posting a copy of a document published in 1937 and
practically incorporated by reference in every FCC licensed broadcast
station's proof of performance.

They can't prove any financial harm, except maybe they didn't sell a
copy of the document for $25 and even at that there is some
possibility that the usage is "fair" in that it's for "research
purposes", do you think they will sue?

Section 107 of the Copyright Act of 1976. Limitations on exclusive
rights: Fair Use

Notwithstanding the provisions of sections 106 and 106A, the fair
use of a copyrighted work, including such use by reproduction in
copies or phonorecords or by any other means specified in that
section, for purposes such as criticism, comment, news reporting,
teaching (including multiple copies for classroom use), scholarship,
or research, is not an infringement of copyright.

I'm building a few yagis for 432 and two meters and need a source for stainless steel push on retainer rings, sometimes called push nuts (incorrectly) to fit element diameter of 3/16" aluminum rod. I know they are made but cannot find a source searching with Google. Any help here would be appreciated. I have the spring steel variety but they rust after 2 or 3 years so the antennas have to be taken down and the retainers replaced.

Thanks and 73,
Ken, KC4IH

Given a 396 meter length of Radio Shack RG58. At 250 kiloherz TLD says
(after some manipulation) that it has a propagation constant of
689.6 X 10^-9 + j7.933 X 10^-3. Zo is 50 -j4.344. Feed it with a
voltage source of 100 volts with a source resistance of 50 ohms.
Put a load on it of j50 ohms. The voltage reflection coefficient at the
load is -4.116 X 10^-3 + j1.091. The absolute value of this number is
1.091, a number greater than one. The power into this line is .1088
Watts. Fine. However, if I calculate the power at the middle of
the line, I get -34.42 watts, a negative number. Moreover, the SWR
calculated at the beginning of the line is -23.21.
What is negative average power?
What does a negative SWR signify?

Hi Owen,
It is too good to be true. (Just consider it came from an unusually
good batch.) The whole exercise is nonsensical, though,
because it results in negative power and a negative SWR. Increase the
loss to a more realistic value and the negative power goes away as
does the negative SWR while the absolute value of the reflection
coefficient is still greater than 1. I was hoping I could get some
kind of nut philosophical justification for negative average power
out of Cecil, but you sprang the trap.

Walter Maxwell, W2DU proposed a fast way to determine earth loss at radio frequencies without digging into the earth.

"Earth Constants", conductivity and permittivity, affect ground wave propagation and terrestrial reflections.. They may predict or explain some propagation. They al;so affect operation of nearby antennas.

Earth permittivity is the ratio of a capacitor`s capacitance using an earth sample as a dielectric, to its capacitance using air as the dielectric. Under "permittivity" my dictionary says: "-See Dielectric Constant.".

Earth conductivity is defined as the conductance between opposite faces of a unit cube (usually 1.0 cubic meter) of a given earth material, e.g. rock, sand, clay, loam, water, etc. Hoe do you measure this without changing its value?

Conductivity and permittivity are affected by chemical and physical composition, moisture, and temperature (especially freezing).

Earth constants are functions of frequency and antenna polarization. R.F. determination seems best.

Best regards, Richard Harrison, KB5WZI

If you go to the mfj website http://www.mfjenterprises.com and look at
their antenna tuners, you can download the instruction manuals for
them. The general adjustment instructions for their 2/capacitor/1
inductor tuners will work fine for you -- try the manual for their
989c tuner.

Don't know of a source for stainless steel in that size, unfortunately.

www.smallparts.com has retaining rings in stainless, but not for
anything smaller than 1/4" diameter. Their RE series is zinc-plated
spring steel, with the exception of the RE-02 and RE-03 (the latter is
for 3/16" shafts) which are beryllium copper. Perhaps this latter
would do, if you coated the aluminum rod with a copper-to-aluminum
compatibility compound to reduce electrolytic interaction?

Inductors are lossy. Capacitors are not. Use the tuner settings which provide a 2:1 VSWR match or better with the least possible amount of inductance. In other words use the least amount of inductance you can get away with.

Owen,

The HF inductance of a square loop is -

L = 0.8 * H * (Ln(4 * H / D) - 1.467) microhenries,

where H is length of one side,

and D is diameter of circular conductor,

both dimensions are in metres.

There are half a dozen other formulas which at first appear to be different from the above but can be mathematically transformed to be identical. And then there are imperial and metric units.

I got it out of one of one of my old notebooks. It's what I use in my programs. I think I stole it from Terman. And Terman stole it from Grover. So it's sure to be accurate enough for anything you are ever likely to use it for.

It is obviously an approximation because when a large conductor diameter is comparable with a very short length of side, the inductance has a negative value.

As a sanity check, compare it with whatever formula you have used up to now.

Reg, G4FGQ

Let's examine this statement.

First all should note that this is a pi-network. Suggestions to use
an MFJ (tee-network) tuning procedure are wrong.

Here is a random example made up on the spur of the moment.

Assume the load is 20 +j50 @ 14 MHz. SWR = 5.2

Also assume that the tuning capacitor(s) Q = 500 and the inductor Q =
200, both typical values.

A nearly optimum solution, from a match and loss standpoint is:

Cin = 140.3 pF, L = .958 uH, Cout = 333.6 pF.

The input z = 49.69 +j0.03 or SWR = 1.006 , Loss = 0.09 dB.

Now, let's force the inductance to a lower value.

Cin = 422 pF, L = 0.67 uH, Cout = 471.3 pF.

The input Z = 49.6 -j0.04 or SWR = 1.008 but the loss = 0.18 dB.

The loss doubled when the inductance was lowered.

All of this is easily calculated using a free tool: XLZIZL.xls.

Reg, G4FGQ wrote:
"How is it done?"

We have to do it within the USA broadcast frequencies with the following method.

The site of the transmitting antenna is plotted on a very accurate map.

Pick map sites along radiaal lines from the antenna which are accessible and free from possible reradiation sources (hard to do within a city) but many sites along a radial will work.

For a single-tower, the nearest measurement site should be at least 5x the tower height away. For a directional array, the nearest measurement site should be at least 10x the widest gap between towers in the array. You need to be far enough away so the antenna system appears to be a point source.

You need to make a log of the measurements you make, showing the site distance from the transmitter, measured field strength, time and conditions which influence the measurement. You need to be able to duplicate the measurements. You would prefer to make the first set of measurements with the antenna operating in a nondirectional mode even if it normally does not operate nondirectionally, so you can determine efficiency very simply.

The more sites and measurements, the better. 25 measurements along each radial is often considered enough for a nondirectional antenna. 40 or 50 would be required 9in a directional array, as the number of radial measurements needed depends on the complexity of antenna system and its pattern.

After completing measurements along a single radial, they should be analyzed to determine the effective field at one mile from the antenna, and the effective ground conductivity.

Fortunately, the FCC publishes charts are made a part of the rules in Part 73 of the FCC Rules. You have likely seen reproductions in many textbooks. I have an old copy of all the groundwave field intensity versus conductivity charts which divide the AM broadcast band into frequency segments.

These FCC charts contain more information than we can use, but they also have what we need.

At the top of the chart is a straight line that shows how the signal would be attenuated over perfectly conducting earth. The field strength

value at one mile is 100 mV / m. At 2 miles, it`s 50 millivolts / m, and so on. This is as expected as over perfedt earth the signal varies inversely with distance from the transmitter.

Beliw the straight line on the chart is a family of curves, each dedicated to a particular soil conductivity. There is a curve for sea water, 5.000 millisiemens (millimhos) and there is a curve for about as nonconductive soil as is found (0.5 millisiemens), and there are several curves in between those extremes.

All of the FCC curves are based on 100 mV / m at 1 mile, but can be scaled. If your transmitter delivers 500 mV / m at 1 mile, aimply multiply all points on the curve by 5.

We want to find the conductivity of our earth. It can be different on every radial parh from the antenna.We find conductivity by plottibg our measured field intensities on translucent graph paper with grid lines which match the fcc graph. Then we line them up and place them over a light source. We can see which of the FCC curves our points most closely follow. It`s labeled ewith its conductivity.

Best regards, Richard Harrison, KB5WZI

Try M2 (http://www.m2inc.com) or Byers chassis kits (Google on the
name; the catalog is .gif images, the retainers are on the last page).
DXEngineering may also carry them.

so if in my transmision thier is of course volts, and waves

if the waves have the ability to generate it, how can their be no volts
or amps in the wave? what force has it how did it get seperated from
the 'volts'

is it making volts from the pure wave energy which in turn moves the
electrons?

so therefore that means when i measure volts in my coax, it's because
the waves produced it my moveing the copper's electrons?

Just thought I would plumb the vast experience of you all before I lug this bad boy on either my 20 ft garage or on the 35 foot roof of my house.

I am torn between setting this up as a ground mount with the usual ground radial system or to set it up as a roof mount with the Butternut stub-tuned radial kit. If the radial kit gives good performance it might be worth it to try to deal with the roof mount as I do get the antenna up over the trees with this configuration.

Anyone had any luck with this set up?

Thanks,

ME

> the 'volts'

I think maybe what Richard is trying to say is that the wave
actually consists of an E-field and an H-field. The E-field
results in volts and the H-field results in amps. The charged
particles responsible for the voltage and current cannot move
at the speed of light.

Probably a more modern way of saying the same thing is that
RF waves are photonic energy, moving at the speed of light.
The photons are the fields and the fields are the photons.
Electrons cannot move at the speed of light. Photons generated
by excited electrons are what move at the speed of light.

In 1619, Kepler proposed that it was the pressure (momentum)
of sunlight that blows back a comet's tail. Maxwell, in 1873
said: "In a medium in which waves are propagated, there is a
pressure (momentum) in the direction normal to the waves ..."

From "Optics", by Hecht: "One of the most significant properties
of the electromagnetic wave is that it transports energy and
momentum." ... "Indeed, whenever we have a flow of energy, it's
reasonable to expect that there will be an associated momentum -
the two are the related time and space aspects of motion."

And, of course, energy and momentum are two things that must
necessarily be conserved. The bottom line is that if there
are any reflected waves that don't reach the source (and also
are not dissipated), they must necessarily have had their direction
of energy and momentum reversed back toward the load. Anything
else would violate the laws of physics.

The sign of power can indicate direction as in:

Pnet = Pfor - Pref

or destructive interference as in:

Pnet = P1 + P2 - 2*SQRT(P1*P2)

Negative power is a fallout of the math model being used.
For instance, V*I*cos(theta) is negative when theta=180 degrees.
theta=180 degrees for reflected power.

If you have a windmill generator connected to your house
power wiring, you can cause your watthour meter to run
backwards. By convention, that would be negative energy
consumption.

No experience with it but Bencher now offers a counterpoise for the
Butternut which may help. I ground mounted my Butternut about a dozen feet
from my operating position and that resulted in some difficulty with RF in
the shack messing with my computer. So whatever location gets the antenna
farthest away from the operating position is the one I would recommend.

Well, you are right I was fooled by your statement "Given a 396 meter length of Radio Shack RG58" which seemed to say a real cable.

I suspect the source of "negative power" values stems from the assumption that Power=Real(Vf*If*-Vf*Ir*), whereas it is my understanding that the power flow at a point on the line is Real(V*I*) or Real((Vf+Vr)*(If-Ir)* which expands to Real(Vf*If* - Vf*Ir* + Vr*If* - VrIr*) so that when Power=Real(Vf*If*-Vf*Ir*) is assumed, two of the terms (- Vf*Ir* + Vr*If*) are being ignored.

The real part of (-Vf*Ir* + Vr*If*) is zero when Zo is real, so they can be ignored for calculating real power when Zo is real.

In the case of your example, but using real RG58C/U (and Zo is not real), it looks to me like Real(Vf*If*-Vf*Ir*) is negative out to about

60m from the load, but Real(V*I*) is always positive and always grows toward the generator.

A graphic showing the behaviour of the terms is at http://www.vk1od.net/RG58sol.gif .

Owen

PS: My notation: the * postfix unary operator means complex conjugate, ie (If-Ir)* means compex congugate of (If-Ir).

If you are having trouble viewing the gif file because it has been zoomed to fit in the browser window, most modern browsers allow you to zoom it up to 100% size.

In Windows Exploder, hold your cursor over the image until a little "Expand" control appears, click the "Expand" control and there you go.

In Firefox, just click on the image.

Would it be at all useful to look for some stainless springs
of the correct ID so that they could be "screwed" onto the elements,
kind of like those internal thread repair kits have, only exernal? I'm
not sure how or where youi'd use them, but they could be combined with
washers if they're too flat when in place.

>

I meant to also mention the response of a typical reflectometer.

The type of reflectometer that samples the voltage at a point, and the current at the same point to create a voltage proportional to that current, (such that the magnitude and phase of the voltage due to the current sample is equal to and opposite to the voltage sample when the line is terminated in its characteristic impedance,) then adds the two voltages algebraicly and measures the magnitude of the resultant responds to Vr, or if it is turned around, to Vf. Such an instrument does not respond to the two cross product terms terms discussed in the quote.

So even if you adjusted such a reflectometer so that it nulled on the true Zo of the cable by adjusting the phase and amplitude of the voltage same wrt current sample, it would respond to Vf and Vr and could not be scaled to read forward and reverse power (since it doesn't respond to the cross product terms).

So, in Tom's case (though with real RG58), a reflectometer of that type, properly nulled and scaled in Watts would indicate more reflected power than forward close to the load. The instrument is correctly responding to the magnitude of the reflection coefficient, but scaling in Watts can only be valid for Zo real.

Hi Richard, you deserve an A+ for your excellent presentation on the use of the FCC charts of signal level vs distance and conductivity. You've described the method exactly as I have used it for single tower BC antennas. I still have a complete set of the charts from 550 KHz to 1600 KHz that I used during the late 1940s, when I was doing AM BC antenna work.

Hi Richard,
mea culpa, only what I posted was more parody than
science. At least it was meant to be. Nothing, short of
a visitation by The Creator will make some of the correspondents
to this newsgroup change their thinking about how transmission
lines behave. However, for those who aren't sure of whether
they're right or not, the contemplation of absurdity may
sharpen the understanding. (Or it may not. I'll try not to
post things like this in the future, but can't guarantee
forebearance.)

I don't recall any changes. The pi (and tee and other) network(s),
having three reactances, allow(s) the operating Q to be set by the
choice of component values. Efficiency is a function of the ratio of
operating (loaded) Q and the unload Q of the components.

For a single reactor it is: eff = Qu / (Qu + Ql)

Clearly, for highest efficiency (lowest loss) you want high unloaded
Q(s) and a minimum loaded Q. By reducing the inductance below an
optimum value, the unloaded network Q was increased, resulting in
lower efficiency.

My two cents worth:

Used an HF9V at 20 feet with no radials for quite a while. Great SWR,
and gave me good results on both transmit and receive.

Used a trapped vertical - 5-BTV I think it was - on top of a five story
apartment building with no radials at all, and it was dynamite!

Why not put it on the roof, tune it, try it out, then add the radials if
you find/feel you need them?

==========

- - - - and since soil resistivity decreases with increasing
frequency, and the impedance due to soil capacitance also decreases
with increasing frequency, everybody agrees that 1/8th wavelength or
less is more than long enough.

And if that isn't enough, the velocity of propagation along buried
wires is considerably slower than the free-space value. It depends on
moisture content and permittivity.

The attenuation due to skin effect and wire inductance along lossy
radial wires is rather high. There's negligible current flowing in
them at distances greater than 1/4-wavelength at their own velocity.
The wires may just as well not be there.

Finally, as the wires spread apart, at appreciable distance
practically all the remaining current flows in the soil because the
cross-sectional area of the soil is far greater than that of the wire.
The longitudinal impedance of the wire is greater than that of the
soil.

The foregoing applies to low and medium resistivity soils. In arid,
sandy, rocky, cactus-growing soils, with resistivities greater than
5,000 or 10,000 ohms-metres, buried wires have low attenuation, they
become resonant and develop standing waves. It is then a good idea to
consider changing from vertical antennas to horizontal dipoles.

The effects can be estimated by calculations on model radial systems.

It may have been noticed that ground loss is least at low and very
high resistivities. So there must be a maximum loss at some
resistivity. I wonder if maximum loss occurs around 377 ohm-metres
after taking the reflecting angle into account?

If B. L & E, made any errors, they made sure they erred on the safe
side regarding numbers.

Message-ID: <if7ob19hbqrjujpo8moi6evcnou8f080n0@4ax.com>
Source record: 74330

Hello...

Will an antenna rotator like a Radio Shack or Channel Master work if hung upside-down from a roof beam, or should I try to come up with a way to secure it to the attic floor?

I know rotators are designed to handle a certain weight, but I can't guess at what they'd do with a "negative" weight...

The antenna I'm looking to rotate is a Channel Master 8-bay bowtie. (CM4228)

Thanks,
-Bob-

Hey Tom, what do you think about Ramo & Whinnery's assertion
in _Fields_and_Waves_... 2nd edition, page 291 " .. we are
often most interested in the ratio of power in the reflected
wave to that in the incident wave, and this ratio is given
by the square of the magnitude of [rho], as can be shown by
considering the Poynting vectors: Pz-/Pz+ = |rho|^2 (3)"

Note the plural "Poynting vectors", Pz- for reflected power
and Pz+ for forward power.

Could Heisenberg be certain that Heisenberg was Heisenberg? Was he certain that the Uncertainty Principle was in itself certain?

Damn, Physics and Philosophy getting all mixed up!

VSWR is real! Deal with it.

VSWR isn't a REAL problem! Deal with it!

VSWR is real and ENGINEERS and Ham Radio operators make transmission lines and antennas work; while Physicists wonder if it's real or uncertain. [My 80 meter antenna has a VSWR of >30:1. It works just fine!]

You've got a point about "negative" weight". Many rotators support
their load on the upper assy which, in turn, runs on a ball-bearing
loaded raceway. Probably a poor pratice to operate them upside down.

What you could look for is a rotator that permits the mast to run
clear through the whole works. These are often used in conjunction
with a separate load bearing supporting the weight of the mast below
the rotator. With a rotator such as this, you can mount the rotator
high in the rafters and run the mast _down_ from the _upright_ rotator.

It's a thought...

====================================

Matching networks, with 2 C's and 1 Coil, can be either Pi networks or T networks. The Pi network, with the coil in series, also behaves as a low-pass filter and for this reason it is to be preferred. But the T network has more convenient and therefore less expensive values of L and C. So for economic reasons manufacturers sell more T than Pi networks. Pi-networks have considerably larger coils and capacitors, but in general they are equally efficient when working between the same transmitter and antenna impedances.

As has already been pointed out, with a T network, 2 series C's and a shunt coil, least loss nearly always occurs when the coil, in conjunction with the C's has it's lowest inductance. But component settings are quite uncritical.

Problems occur only when one or other or both of the capacitors are very near to their minimum settings, ie., little more than stray capacitance remains in cicuit. The capacitors may then arc over (which is immediately apparent). Or the coil turns may become overheated when attempting to run 1 Kwatt or more (which may take a minute or so when operating CW or FM).

I mention overload circumstances only because the effects and worries are too often exaggerated in these newsgroups. So don't lose any sleep! Even if half the power is lost in your tuner your signal strength falls by only 1/2 of an S-unit.

To become familiar with series T-Match Networks download program T_TUNER from website below. Any impedance R+jX can be matched to any other R+jX. But usually the Tx or generator impedance is a purely resistve 50 ohms which simplifies understanding of what's going on.

Other practical programs, from the very few I've seen, only manage to match two purely resistive impedances. Which with radio antennas seldom exist.

Download program T_TUNER in a few seconds and run immediately. Go from "Index" to "Download Progs from Here" page and run immediately.

There are several other programs of various sorts which include operation and component values of T and L-match transmitting circuits. If you are accustomed to calculating how many rolls of wallpaper are needed to re-decorate your shack then you will feel at home.

Anything will work after a fashion. It's no proof of anything.

It is not realised by many amateurs and engineers that the so-called SWR meter does not measure SWR. It merely indicates whether or not the transmitter is loaded with its design resistance. Which, of course, is useful.

The meter not located in the right place to measure SWR on the feedline. The feedline on which it is imagined SWR is measured does not exist.

To measure SWR on any line a moving voltmeter is required. SWR is simply max volts divided by min volts which occur at a distance apart of 1/4-wavelength if the line is long enough, and requires no knowledge of line impedance or its terminating impedances, or of anything else about the line.

In other words, SWR is just something for Old Wives and "clever" people to plagiarise and waffle about, on newsgroups and in the magazines, and so continue to mislead themselves together with the unfortunate learners, CB-ers, and the novices.

I used the complicated expressions for V and I found
in _Field and Wave Electromagnetics_ by David K. Cheng on page 468,
and then found the power by taking the real part of VI*. If you're
interested in doing it the hard way, you can first find V and I,
then take (V + ZoI)/2Sqrt(ReZo) and call that a. Then take
(V - Zo*I)/2Sqrt(ReZo) and call that b. The power is then just
|a|^2 - |b|^2. This last comes from _Microwave Engineering Using
Microstrips_ by E.F. Fooks and R.A Zakarevicius.
Before doing any of this, though, be sure the propagation constant
is the right one for the Zo of the line. The books give
the propagation constant for a transmission line as sqrt((R + jwL)(G +
jwC)), and Zo as sqrt((R + jwL)/(G + jwL)) so it's reasonable to assume
the two are related. In other words, it doesn't seem as if you can just
pick numbers out of a hat for the two quantities and expect them to mean
anything.

"If the waves have the ability to generate it, how can there be no volts or amps in the wave?'

Good question. We know light, an EM phenomenon, travels to us over zillions of miles and years through a medium of sparce and scattered conduction when there is any. The answer is fields which need no conduction, yet still exert action at a distance.

James Clerk-Maxwell speculated that the kind of current you have in a capacitor, displacement current, which does not require electron migration, was responsible for propagation in free space, no "aether" necessary. Maxwell was right.

Two of Maxwell`s equations are called his field equations. The first equation says that a changing magnetic field produces an electric field. The second says that a changing electric field produces a magnetic field.

That is the secret of electromagnetic radiation.

For more details see "Radio-Electronic Transmission Fundamentals" by B. Whitfield Griffith, Jr. He explains dot products and contour integrals too.

Best regards, Richard Harrison, KB5WZI

Larry, what do you mean by 'offset'? Do you really mean 'off-center fed'? If that's the case the only reason one would want to feed an antenna off center would be if it permitted a better chance for a 90° angle between the antenna and the feedline from where the feedline enters the house.

A dipole is a dipole, no matter how it's fed, center, off center, or end. The only difference in the radiation pattern between the various methods of feeding is the re-radiation effect of the feeder if it's not in a neutral portion of the radiation from the dipole, causing current to flow on the feeder and thus radiating in addition to that of the dipole.

The dipole fed at the center with the feedline coming away from the dipole at 90°, the feedline will not be a part of the radiator, unless the feedline is coax with no balun. The balun prevents antenna currents from flowing on the outside of the coax shield, thus preventing radiation fromthe feedline.

Incidentally, the spelling is baluN, not baluM, the term coming from the combination of two words, BALance to UNbalance.

I know the closer you get to the roof, the smaller the permissible turning radius, so maybe you need to cut through the attic floor and attach the rotator to the side of a joist. There might be 6" more room that way.

BB> -Bob-
BB> N1GYL

I think it might work because rotators are rated for a large wind load
and hanging upside down doesn't even seem to come close to that.
However, I'd call the mfr first to ask for their recommendation
before doing it. I doubt any gears in the rotator depend on gravity to
stay in place. OTOH do you think fix mounting the rotator shaft and
having the antenna hanging off the mast fixture instead might work?

Hi, Larry,

An off-center fed antenna doesn't necessarily produce unbalanced feeder currents - - just a different feeding impedance level, which he will no doubt take care of with a tuner or a 4:1 ratio in the balun if single band use is all he wants and he can find the right spot for the feeder. Of course the balun takes care of any unbalance that might be due to the feeder not making a 90 degree angle with the antenna. There's nothing wrong with his idea.

I just typed it balum, too, so don't be concerned - - we all make typos.

I can think of a couple more. One reason would be
to achieve a reasonably good match to the antenna
on more than one band using coax and no transmatch.
Another reason is that an off-center-fed dipole tends
to have a broader SWR curve than a center-fed dipole
(coax feed and single-band operation assumed).

That's easy for you to say.
I can make out the word 'antenna', and 'Dell' and something like
Rice-a-Roni.
So - to answer your question -
If you spill Rice-a-Roni on your antenna, it won't hurt too bad, but it will
probably hurt the Dell computer.

I looked in Terman, but didn't find it, and still can't. I might be blind!

I got it from http://emcsun.ece.umr.edu/new-induct/ but it obviously
shares the same root as yours. They attribute it to Grover.

See above. I think you are telling me I should be confident I am sane.
If it was just that easy!

Now I just have to find someone with access to an OATS to measure one of
these things.

Thanks Reg...

On Fri, 24 Jun 2005 17:04:26 -0700, Richard Clark <kb7qhc@comcast.net>
wrote:
>Ptolemy (85-165)
Something from his Almagest, Book 1, that is vaguely descriptive of
someone we all know and love:
"Well do I know that I am mortal, a creature of one day.
But if my mind follows the winding paths of the stars
Then my feet no longer rest on earth, but standing by
Zeus himself I take my fill of ambrosia, the divine dish."
This epigram follows the table of contents as something of a
self-dedication (also a mannerism we are familiar with).

Ptolemy also reduced much of his theory of Astronomy and Optics to
geometric construction techniques in many Handbooks and offered scads
of tables of observations - some of which were condemned by Newton:
"[Ptolemy] developed certain astronomical theories and discovered
that they were not consistent with observation. Instead of
abandoning the theories, he deliberately fabricated observations
from the theories so that he could claim that the observations
prove the validity of his theories. In every scientific or
scholarly setting known, this practice is called fraud, and it is
a crime against science and scholarship."

There still remain some high Q resonances with that condemnation.

Well, the validity of that accusation has to be judged in light of
Newton's own flamboyant fudging of "observed" times for the speed of
sound forced-fit into his own theoretical work. Those errors are so
stunning that Isaac must've thought no one would ever discover them
while reading his sleeping pill.

There've been a lot of grave robbers that have come down the pike
since that fall from grace in the garden.

> currents - -

I'm sorry to say, it does. There's coupling from the feedline to each side of the antenna, and unlike a symmetrical dipole with feedline at right angles, the coupling from each side is unequal. This results in unbalanced feeder currents. If the feedline is twinlead or open wire line, this shows up as unequal currents on the two conductors. On coax it manifests itself as current on the outside of the shield. In both cases, the result is the same -- feedline radiation.

This can be shown quite dramatically by simple modeling. I've also seen it myself by direct measurement(*). A current balun (NOT voltage balun) at the feedpoint will reduce the conducted common mode current just as it will with a dipole, but you still have to deal with common mode current due to coupling. Depending on the frequency and the feedline length and orientation, you might get lucky and not have too much feedline current. On the other hand, it can be bad enough to aggravate RFI problems if the feedline is routed near power or telephone lines, or cause trouble with your rig or shack accessories.

> just a different feeding impedance level, which he will no
> doubt take care of with a tuner or a 4:1 ratio in the balun if single band

> the balun takes care of any unbalance that might be due to the feeder
> not making a 90 degree angle with the antenna. There's nothing wrong
> with his idea.

See above comments. Routing the feeder at right angles to the antenna doesn't eliminate current due to mutual coupling, and neither does a feedpoint balun.

>. . .

(*) You'll find some measured values of feedline current and more discussion about it in "The Off-Center-Fed Dipole Revisited: A Broadband, Multiband Antenna" by John Belrose, VE2CV and Peter Bouliane, VE3KLO, QST, Aug. 1990.

How ironic! I recall an article in _Scientific American_ many years ago which presented credible evidence that Newton himself fudged his data. The author argued, and gave examples to show, that some of Newton's data were much too accurate and consistent for the techniques and equipment he used.

Just catching up on things a week or so after the post you made.

I suspect you have 3 EE degrees because you stated such, so you are obviously worlds smarter than I am, especially if it's from a "top 5 school", but since when does a coax choke balun cause loss of anything except feedline radiation, which you don't want anyway?

Reg, do you really mean what you said above, 'soil resistivity decreases with increasing frequency'? Are you sure you didn't mean soil conductivity decreases with increasing frequency? In my experience with AM BC antennas I've found that conductivity decreases, not resistivity.

The FCC charts showing signal level vs conductivity and frequency overwhelmingly show conductivity decreasing with frequency. So you ask, what proof is there that the FCC charts are correct? Well, Reg, soil conductivity measurements of thousands of AM antenna systems world wide have proved them correct.

As an example that I posted a few days ago, consider the coverage area from afforded by a single 1/4wl vertical radiating 250 watts at 550 KHz with a signal strength of 1 mv/meter at one mile and a conductivity of 8. If the frequency were raised to 1500 KHz with a 1/4wl vertical at that frequency, the power required to cover the same area is 47 KW.

Does this example indicate a decreasing soil resitivity with increasing frequency or a decreasing soil conductivity?

Source record: 74365

I'm not quite clear what you are talking about, but the impedance seen looking into the feedpoint of a 1/2-wave resonant dipole when the feedpoint is at the centre, is a purely resistive 70 to 73 ohms.

As the feedpoint is moved away from the centre the impedance rapidly increases (approximately proportional to the square of the offset) BUT REMAINS PURELY RESISTIVE until, as the feedpoint nears the end of the dipole, it rises to several thousand ohms, purely resistive.

This is the impedance which terminates the twin feedline. But if there is a choke in the line at this point then the choke can be considered to be a short length of line of the same length and Zo as is wound on the choke.

The short length of line on the choke will then TRANSFORM the antenna input impedance to a somwhat different value to terminate the line. (For the purpose of calculating SWR on the line, and the line's input impedance, etc.)

Now carry on from there. ;o)

Source record: 74366

... and, while I may have misplaced the place where this happened (I could have heard this when I was at U of Manchester), it seems that an extensive set of early measurements of c were deliberately "sorted" and produced an expected value and std that was outside of the actual value of c. When the logbooks containing all of the measurements were consulted many decades later, it was found that if one used all of the measurements the actual expected value of c was within the expected error.

It is late and I have not quite said everything right. The (old) published expected c and its std were well outside of the actual c. When the old data was used in its entirety, the newly calculated expected c and its std encompassed the actual value of c. (Note "expected" has a technical meaning.)

The moral is to keep a complete log and be honest. It is much more easy to do both when one has numbers. Before some of my work at Ohio State, one had to extract numbers from strip chart recordings using slave labor.

Walter,

Your ancient charts, which I think I have once seen but don't now have ready access to, apply to LF. Permittivity was ignored when they were calculated. The curves were intended to be used as a guide, better than nothing, rather than the Bible on the subject.

But amateurs are concerned with what happens at HF. There are a lot of MHz between 16 KHz, 500 KHz and 40 MHz

I think the discrepancy about conductivity vs frequency is due to simplification of the equivalent circuit of soil which, in its most simple form, is a resistor in shunt with a capacitor.

As frequency increases the capacitative impedance decreases and drags the equivalent resistive component down with it. There is a significant decrease at around 7 MHz. At 30 or 40 MHz the soil has changed from being mainly resistive at LF to being mainly capacitative and not nearly so lossy.

The capacitance between a pair of 1 metre square plates, spaced 1 metre apart, is only 8.8 pF. But when muliplied by the permittivity of damp soil the impedance at 30 MHz is quite low. The permittivity of water is 80.

Simple conductivity does not apply. We are not talking about the same things.

Actually, its not worth arguing about. The uncertainty in soil characteristics is plus or minus 30 or 40 percent. And it makes less than 1 S-unit difference to the performance of radials and Eznec take off angles at HF. No doubt Roy will disagree as a matter of Boston Tea Party principles. And Richard, KB7QHC, will spin off at a tangent into Shakesperian verse.

Hope this clarifies my Altzeimer's thoughts on the matter.

Hi Reg,

Let's draw a chord between 3 soil samples to see how fruitless knowing
"How to measure soil constants at HF" really is:

You are in farm country where the annual rainfall is 835mm. Where the
mean temperature is 12.8ï¿½C. Where the soil is 20% sand, 65% silt, and
15% clay.

What is the Conductivity in the 80M band?

You are in farm country where the annual rainfall is 360mm. Where the
mean temperature is 4.9ï¿½C. Where the soil is 65% sand, 20% silt, and
15% clay.

What is the Conductivity in the 80M band?

You are in farm country where the annual rainfall is 790mm. Where the
mean temperature is 6.9ï¿½C. Where the soil is 31% sand, 33% silt, and
36% clay.

What is the Conductivity in the 80M band?

OR

We return to our regularly scheduled "More Les Dames d'Escoffier
Recipes with your host Punchinello." Today we discuss packing coaxial
tubes with meringue to measure propagation delay for custards.

I don't know. And neither do you or anybody else.

If you DID know you would not have the foggiest idea what to do with the data anyway. I might!

Havn't I recently said the uncertainty in ascertaining soil characteristics is in the order of 30 to 40 percent and not worth arguing or making yourself appear ridiculous about.

There's missing data. You forgot the iron oxide content and soil permeability.

Punchinello.

>
You don't need to "think quantum things" about this problem.

The discovery of quantum physics was that energy levels aren't continuous. A "system" (whatever it may be) can only have certain levels of energy - in-between energy levels are not allowed. To change between energy level, the system must emit or absorb quanta of energy.

Quantum energy E is related to frequency (f, Hz) by E = h*f, where h is Planck's constant = 6.6 x 10^-34 Joule seconds.

At 10MHz, the quantum energy is 0.000 000 000 000 000 000 000 000 0066 joules. This is so small that - for all practical purposes - ANY energy level is possible, and quantum effects at radio frequencies are so small they are irrelevant.

So quantum physics has just *confirmed* that, at radio frequencies, classical EM physics is all you need to know.

>hey people thought people like einstein were nutz too and he was smart
>
The question is: are there any Einsteins here?

Antennas and transmission lines are home territory for classical EM physics, right in the middle of our map of existing knowledge. There are still lots of interesting new things to be discovered there; but we know in advance that they MUST join up with the existing map, because it surrounds us on every side.

Anybody who imagines he's an Einstein, exploring the outer boundaries... is just plain lost.

1808. Correct cable for 920Mhz Mobile, Yagi

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-25 09:19:42 UTC
From: Mark
Message-ID: <et7qb1la2lr29hpnu0741kv79ii9ecj2c8@4ax.com>
Source record: 74373

Please could somebody tell me the best cable (compromise between cost and loss) for use with an external Yagi antenna connected to a mobile phone. I live in a Very poor reception area, and I need to fit an external antenna. I have found somewhere that sells 10 element Yagi's, and I can mount the thing as high as need be, but I read somewhere that the longer the connecting cable, can negate the benefits of long mounting poles. I have freinds in the surrounding area that have the same problem, so I could do with a "rule of thumb" that I can use for fitting these things. The shop where I got the antenna from is offering me RG58 cable for this purpose, which is cheap enough, but is it the best compromise for what I am trying to achieve? Your assistance would be most welcome.
Mark

> The wires may just as well not be there.
> . . .

I'm afraid your oversimplified model of how radials work has once again led you astray. B, L, & E's measurements show the following:

For an 88 degree high vertical, where n is the number of radials, the following fraction of the current at the center is flowing in the radial 1/4 wavelength (at a velocity factor of 0.2, the approximate VF in the radial's environment), from Fig. 42 of their paper:

n Fraction
15 0.67
30 0.68
60 0.90
113 ~ 1.0

1/4 *free space* wavelength from the center:

n Fraction
15 0.19
30 0.14
60 0.26 [This is a minimum; it rises then drops further out]
113 0.61 " "

Note that the results are quite different when the radiator is only 22 degrees high (Fig. 43) -- the resonant effects apparent on the 60 and 113 radial measurements are absent, and the currents decay monotonically. There isn't nearly as much difference between 15 and 113 radials. But with 15 radials, the current 1/4 in-ground wavelength from the center is still about 67% of the current at the center.

Again I see evidence that your analysis overlooks the interaction among radials. There's less interaction when there are only a few, but even with 15 your analysis has led you badly astray. And does it account for the considerable differences with different radiator heights?

But I've pointed this out to you before yet you keep promoting this myth, so I guess you just don't want to be confused by the facts.

> If B. L & E, made any errors, they made sure they erred on the safe
> side regarding numbers.

One of their key results is that ". . .the ground system consisting of only 15 radial wires need not be more than 0.1 [free space] wave length long, while the system consisting of 113 radials is still effective out to 0.5 [free space] wave length."

Their results agree reasonably well with NEC-4 modeling. But I'm sure glad we've got you to set us straight about how well they did and how they could have improved their methods. You've surely got a clearer perspective, not having been prejudiced by actually reading their paper.

Oops, here I am nitpicking again -- pointing out that .67 doesn't equal zero.

thanks for responding Ian:

No doubt your correct about alot, and clasically speaking i wouldn't argue, however 2 points

firstly my comparsion to einstein wasn't regarding myself i was making a joke that my 'theories /ideas' are often thought of as crazy but who knows

regarding your being so firm saying that rf is typically just conventional physics, I dunno..
who says it's confirmed to our space??

we are only just begining to see the possibilities that things in our deminsion/ or time "e space" do in fact have relationships with 'other ' things, some of which might be having effects out of phase, 'time' or having somthing corresponding in another dimension so to speak (for example)

it's not unfathomable to think that the sum of our current knowledge might no be infinate, perhaps we've simply failed to measure ? who knows what tomorrows proved new theories will bring?

already here waves(rf) conventional were compared to photonic 'energy'(now thats something few can understand alone) and those photos do some really strange things w/regards to the above (even more strange)

conventionally speaking your correct of course, but i always keep an open mind towards possibilities, and crazy theories, since rf is still such a not understood umm blackhole or i am just crazy

yeah i am just a nutty non scientific type throwing wackey ideas i have into that round black hole hoping that i'll find the right sized peg(my best asylm analogy rich) not cause i want to be known, but it's just fun for me to ponder these things

i've already learned alot from you ian thanks again rich and cecil thanks too

One conceptual mistake that a lot of people make concerns
the roll of free electrons in a transmission line. It is
the fields/photons that move at the speed of light, not the
electrons. EM energy stored in excited free electrons is
unstable and fleeting. The electron always gives up that
extra energy very quickly in the form of photons which must
necessarily travel at the speed of light and are incapable
of some Old Wives' Tale "sloshing" response.

Just because the electrons are capable of "sloshing" around
doesn't mean that the EM energy can slosh around. The EM wave
energy is not confined to the electrons, it exists ultimately
in the fields/photons in the form of ExH wave energy/time
moving at the speed of light.

Reg, G4FGQ wrote:
"Your ancient charts, which I think I have once seen but don`t now have access to, apply only to LF. Permittivity was ignored when they were calculated."

True, they are not for HF. My edition was reprinted by the Seabrooke Printing Company, Inc. and covers the range ftom 540 KHz to 1600 KHz. Dielectric constant (permittivity) is assumed to be 15 in all cases.

The reason there are graphs for frequency segments such as 1560 kc to 1640 kc is that loss increases with frequency. Skin effect is an important faxtor. The higher the frequency, the less it penetrates the earth, so the crust carrying the r-f is thinner. The decline of field intensity versus distance from the transmitter is steeper at HF.

My set of curves has a page which gives the formulas used to construct "surface wave field intensity versus numerical distance over plane earth". It has separate sets of formulas for vertical and horizontal polarizations. Curves in the book are for vertical polarization, the only thing of interest to a broadcaster.

One option would be to construct your own set of curves. Another would be to find some curves which have already been constructed. I don`t know of any but expect that they exist.

Best regards, Richard Harrison, KB5WZI

Source record: 74282

I cannot recommend a specific cable. But I will say that RG58 is 100% non suitable for use at 920 MHz! RG58 has very high loss and even 100 feet at 920 MHz will loose about 96% of the received signal [-14 dB].

RG8 or RG11 will loose about 1/2 of the received signal. RG8 or RG11 will cost about $0.50 [USD] per foot. Good quality connectors will have to be used.

You might? With emphasis too. Now if that isn't a firm declaration
to end the pursuit in "How to measure soil constants at HF." In
point of fact, you simply validate my premise:

>>Let's draw a chord between 3 soil samples to see how fruitless knowing
>>"How to measure soil constants at HF" really is

As you struggled on:
>There's missing data. You forgot the iron oxide content and soil permeability.

There is so much missing information as: What is it to an average of one skin depth in YOUR garden, old son?

To this point all method and no results. By contrast, Walt provided both, and his data shows a continuity to your pronouncement about the wavelength shortening of radials adjacent to the ground - something you proclaimed no antenna measurement could achieve.

Walt's method necessarily includes one skin depth (and more) that your scraping at the veneer of soil could never model. He doesn't have to worry about temperature, moisture, time of day, season, iron oxide content, or permeability - it comes free with the attempt and you don't have to haul mud into the kitchen. Do I hear John Cleese muttering something about the Bloody Obvious?

If by we, you mean astronomers, and if by things, you mean galaxies.
This is where 34 places begins to add up to serious values, like a
boost of 1 MPH acceleration averaged over 100 quadrillion stars. Hold
the key down on your amplified transmitter for a century, and your
antenna might create as much thrust pressure that a snail expends in a
femtosecond. If quantum effects were significant, then the weight of
one more microbe from a nearby sneeze would immediately crush you as
much as the added burden of Atlas.

Thanks, Reg, for sharpening up the picture on off-center feeding of a wire antenna. And thanks, Roy for bringing out the likelihood of asymmetrical coupling to the off-center feedline and the difficulties that can result.

Roy, surely you realise that all depends on soil conductivity and
permittivity which B, L & E forgot to determine before leaving the
site.

30 years previously, around 1905, Sommerfeld (and others) had produced
a significant report showing the importance of ground characteristics
on radiation and propagation at LF and below. Which B, L, & E ought
to have been aware of if they had known what they were about.

You should concentrate your thoughts on HF and above, not on LF and
VLF distractions. Different characteristics prevail at HF at which
frequencies amateurs are most concerned.

You have thoroughly refuted any intimate knowledge of their paper, it
goes unread by you, and yet you "know" this for a fact. Or perhaps
that is elevating your prose upon to an unwarranted pedestal.

>30 years previously, around 1905, Sommerfeld (and others) had produced
>a significant report showing the importance of ground characteristics
>on radiation and propagation at LF and below. Which B, L, & E ought

However, your earlier reference to LF from Sommerfeld (and others) is
then wholly negated by you with:
>You should concentrate your thoughts on HF and above, not on LF and
>VLF distractions. Different characteristics prevail at HF at which
>frequencies amateurs are most concerned.

Back in 1905, they called the frequencies above 1MHz VHF....

So, our trio, B,L, & E could just as easily had dismissed this work as
you have? Such legerdemain.

Sir Kelvinator asks, "Got any data, Reggie?"

This quality of fence sitting - arguing both sides against the middle
- is classic Punchinello.

It just isn't sinking in, is it? It depends on the conductivity and permittivity to a skin depth or more, which was impossible for them to determine. A surface measurement wouldn't have provided the necessary information. Measurement of ground wave attenuation to another location would have included ground with a variety of possible characteristics different from those in the immediate vicinity.

> 30 years previously, around 1905, Sommerfeld (and others) had produced
> a significant report showing the importance of ground characteristics

> to have been aware of if they had known what they were about.

I'm sure they were. But the paper has nothing to do with propagation. What makes you think it does?

They certainly did know about the effect of conductivity. In a theoretical analysis at the beginning of their paper they calculated expected radial ground currents for several different ground conductivities, and explain how current is distributed in the ground with conductivity being a factor. The radial ground current analysis was later found to be in error(*), but it's still considerably closer than the results I've seen from your analysis and program.

> You should concentrate your thoughts on HF and above, not on LF and
> VLF distractions. Different characteristics prevail at HF at which
> frequencies amateurs are most concerned.

That's a bizarre admonition from someone constantly harping about how many radials American AM broadcasters use. I am indeed most interested in HF, where skin depth is on the order of 12 feet for average soil, and measurement of surface conductivity and permittivity is pretty useless. Incidentally, since you haven't read their paper, you probably don't know that the BL & E measurements were done at 3 MHz, which is HF.

(*) To my knowledge, no one has developed a method of calculating radial currents or ground system losses with even approximate accuracy other than with numerical analysis such as used by NEC-4. Many years ago I spent a couple of years of spare time in a technical library looking for just such an analysis without success. Reg's method is delightfully simple but gives results which are very wrong.

Roy, doesn't this suggest that there is benefit in twisting an open wire feedline to attempt to expose each conductor to similar coupling to the external fields. Clearly the benefit will be better for a higher twist rate. Whilst achieving sufficient twist rate with a wide air-spaced line may be impractical, it is probably quite realisable with ladder line (notwithstanding the downsides of ladder line).

I suspect there is not much one could do to minimise the effects of current on a coax shield other than placement of ferrite suppression sleeves or loops in the coax at several places on the feedline to spoil resonances in much the same way as one would try to prevent parasitic excitation of a guy wire by breaking into non-resonant lengths with insulators.

Source record: 74300
Cross-posted to:
rec.radio.amateur.antenna;,rec.radio.amateur.boatanchors;,rec.radio.amateur.dx;,rec.radio.amateur.space;,rec.radio.shortwave

A friend of mine, Jim Tonne, WB6BLD, has written a much-improved, Windows version of a classic great-circle plotting program and is providing it to the Amateur Radio community FOR FREE.

If you are a DX'er and need an antenna-bearing aid or just like to poke around on the earth's geography, this program will be of interest to you.

It calculates the bearing and distance from a Home location to a Target location anywhere in the world and displays this result on both azimuthal (polar) and rectangular maps. Both the Home and Target locations may be selected by mouse designations on the rectangular world map or chosen from a menu of cities, countries and callsign areas. The Maidenhead grid system is fully supported on both data-entry and readout. Sun and terminator positions are plotted on both maps in real time from the host computer clock, enabled by a menu selection. Both maps use an accurate, high-resolution, up-to-date geographic database. The azimuth map may be plotted at five different resolutions, allowing an optimum mix of accuracy and computation speed. Additionally, the azimuth plot may be repeatedly zoomed-in or out by a factor of 2 to place both Home and Target on-screen. Bearing and range overlays are provided in the azimuth plot, making it suitable for a printed-out beam-heading chart.

Both the polar and rectangular plots are printed to the standard Windows printer, no special drivers are needed. System requirements are a Pentium processor (P4 recommended), Windows 98, ME, 2000, XP, and 4.8 Megabytes of free disk space.

The download installation file size is 2.5 Megabytes. The program download URL is:

http://tonnesoftware.com/pizzadownload.html

There are other programs out there that perform this same calculation, but none with the combination of features Pizza offers.

Oh, yeah, that name. Bring up an azimuth plot of the entire world and it hits you in the eye like a big pizza pie -- that's amorï¿½!

No. The problem isn't that the coupling is different to each conductor of the transmission line, it's that the coupling is different from the transmission line to each side of the antenna. Twisting the line won't change the coupling of this common mode current by any appreciable amount. Unfortunately.

The problem is exactly the same for coax and for two-wire line, and the solution is the same for both -- common mode chokes (current baluns) spaced about a quarter wavelength apart to break up resonances. In practice, implementation is usually easier with coax.

1841. Re: momentum"Sloshing" EM Energy

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-26 02:53:00 UTC
From: richardharrison@webtv.net
Message-ID: <8199-42BE188C-328@storefull-3257.bay.webtv.net>
Source record: 74308

Look at the title of this thread. Why slosh?

Transmission lines are used to convey energy, and at high frequencies they serve as resonant circuits, measuring devices, and impedance matching sections.

Viltage and current at any point on a transmission line is expressed as the sum of the voltages and currents of two waves, one traveking forward toward the load (the incident wave) and one reflected from the load (the reflected or reverse wave).

The reflected wave consists of energy from the wave traveling toward the load which is rejected by the load becausse the voltage to current ratio does not fit the only voltage to current ratio the load can accept, its impedance, perhaps a complex value.

All energy in the wave traveling toward the load and all energy traveling away from the load (the opposite travel direction) must conform to the absolute value of the line`s characteristic impedance (Zo).

Phase of the reflected current traveling back toward the generator is given a negative sign because the reflected wave is traveling in the reverse direction from the forward wave which travels toward the load. (See page 86 in the 1955 edition of Terman.

Phase of the reflected current traveling toward the generator is everywhere proportional but out of phase with reflected voltage. The reflected voltage to current ratio is: -Zo.

Actual voltage across the load is the sum of the incident and reflected voltages. Actual current through the load is the sum of the incident and reflected currents. The vector ratio of load voltage to load current must equal the load impedance which may be a complex value.

The vector ratio of incident voltage to treflected voltage at the load is called the reflection coefficient of the load. It may be obtained from forward and reverse powers at the load. I have a special slide rule given me by the Bird wattmeter people to convert wattmeter forward and reverse indications into a reflection coefficient or an SWR.

The transmission line and its load completely control the volts and amps everywhere in the system driven by a certain generator. There are no renegade volts and amps sloshing around. The idea is preposterous.

Best regards, Richard Harrison, KB5WZI

how many sins can i count...
1. guyed to trees
2. guyed to power pole
3. saddled lots of dead horses
4. two different tower types mixed
5. doesn't look like a proper base... at least not to rohn specs.
6. that mast sure does look too long above the kind of tiny tube top.
7. no thrust bearing
8. too close to power line? probably since its guyed to a power pole.

Reg wrote:
> Walt, did you measure ground conductivity and permittivity?
> Or did you forget like messrs B, L & E.

Wasn't this measurement sequence made close enough to the radiators so that ground conditions were unimportant? The need was to establish the "efficiency" (note) of medium-wave radiators of various heights with ground systems of various configurations to use as a basis for an allocations plan for commercial MW broadcasting. The FCC reviewed and adopted it, and it has served quite well as such for many decades now.

From reading his publications it can be seen that George Brown was a meticulously careful engineer. It is unlikely that he would "forget" anything that was germane to the purpose of this study.

Note: Efficiency in this case meaning the horizontal plane field intensity
at distances close enough to the vertical radiator that ground conditions
and earth curvature can be ignored.

RF

1852. Choke baluns again

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-26 13:37:46 UTC

A choke balun is what is inserted between the transmitter end of the antenna feedline and the transmitte tuner. Or it can be inserted at the antenna end of the line.

Questions : How effective is it? To what extent can the percentage unbalance current on the feedline be expected to be reduced? Has anybody ever measured it before and after insertion?

Reg.

Dear Richard,

Aside from some easily correctable typos, your posting is very readable and cogent. The above paragraph, however, has a rather difficult to understand ending, and I'm hoping you will review it and provide more readable wording.

I can comment on my recent experiments with a half-wave vertical on
10-11 meters.

A current balun (or ferrite beads on the coax) greatly reduce feedline
radiation--seems to have an overall beneficial effects on the antennas
radiation pattern--and seems to "stabilize" the pruning/tuning of the
antenna (things begin behaving in a linear and logical way.)

Mind you, the above is only deduced/measured with a FSM, SWR bridge (of
the type which does NOT work for real measurement of swr but rather
transmitter loading) and observed/known signals from other stations and
the reports given back on my signal from these stations.

While this may be viewed as "crude" by some--it is real world in that
the effects as least "seem" real.

Or, the short form of all this is, "The Current Balun is my friend!"

... yes, I am known to reply to my own posts--far too often...

From all the current baluns I have tried, and I have tried every type I could find, this choke/balun design is my favorite and seems to have the lowest insertion loss of all and seems to exhibit excellent qualities of the type desired:

The only thing I have against them (current baluns) is
They are heavy.
and cause the antenna to droop
lowering the height of the feedpoint.
Which is a good reason to put the balun near the radio and use balanced
feedline from there to the antenna
my 3.5 cents

I just weighed 50 beads that are used in W2DU's balun and came up with
a whopping 4 ounces!

Yea, four ounces should cause one hell of a droop.<G>

Dan:
"Droop?"

Hmm, I have heard about that, brits may refer to it as "brewers droop?"
Or, maybe I am confused here...

However, problem only seems to occur when there are pints involved...
<grin>

Droop is like dB loss - it should be minimized at all costs. :-)

1863. 2 greatest Antennas I have ever had

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-26 19:58:57 UTC
From: RoyaltyFreePhotoMart@gmail.com
Message-ID: <1119815937.147508.13610@o13g2000cwo.googlegroups.com>
Source record: 74228

I have 2 antennas that I an very happy with. These are by far the best preforming antennas I have ever owned.

The first is a 17 METER antenna unlike anything you have ever seen or heard of before.

It is a 17 METER half wave dipole that is constructed in the shape of the letter "C". I first saw this design in the former East German sector about a year after the Berlin wall came down. I happened upon a deserted East German military base that had this huge antenna farm. I thought about it for a number of years and then began experimenting with it...and came up with a real winned.

As I said, it is a half wave dipole that is constructed in the shape of the letter "C". The vertical part of the letter "C" is 1/4 wave length attached to a tree with couple screw-in ceramic standoff insulators I got at Home Depot. The upper and lower horizontal parts of the letter "C" and 1/8 wave length. You feed it in the middle of the vertical part of the letter "C" with 50 ohm coax. It is a perfect 1 to 1 match.

Now, this is the IMPORTANT PART and the secret of it's success. YOU MOUNT THE LOWER HORIZONTAL SECTION OF THE LETTER "C" SO THAT IT IS 24 INCHES OFF THE GROUND. This is extremely important because it give is a very low angle or radiation.

ALSO IMPORTANT. Construct this antenna with the largest gauge of stranded wire you can find. Go to the local hardware store and buy the thickest stranded wire you can get. Or, you can also use 1/8 or 3/8 copper tubing. You want to have as much surface area as possible

OK, the SECOND GREAT ANTENNA that I have is a Windom. Now, don't laugh, but this is the 10 thru 40 meter Windom THAT A GUY ON EBAY SELLS FOR $20. I have the thing 35 feet in the air. Feed it directly with 50 ohm coax.

The guy down the street has a G5RV (about $75 or $85) at 50 feet and a Force 12 vertical dipole (about $300) and it blows both of them away. I work stuff that he can't even hear. We both have similar equipment. And being in the same neighborhood, our locations are similar.

That Windom is the best $20 investment I ever made.

they may be forgiven, but that won't keep a tower in the air nor make it
safer to climb. those sins are things you should seriously look at
correcting as they all affect the strength and safety of your investment as
well as anyone working on it or playing near it.

An even better way to setup anonymity is with mail2news and a remailer,
it takes a bit more knowledge and work but is worth it in the long run.
A google should supply one with all necessary details and tools.

Yep, and you'll find it right on the web. Go to
http://eznec.com/Amateur/Articles/Baluns.pdf and read the section titled
"Experiments" beginning on p. 3 of the PDF document. You might also find
some other interesting information in this article.

Warning, though. It was written by an American, so should be regarded
with great suspicion and skepticism.

Reg:

As usual, your posts inspire thought--and that is a GOOD thing.

At least with this type of balun:
http://home.datacomm.ch/hb9abx/pactor-e-choke.htm

I ask, "Why not?" The insertion loss is negligible. The downside of
its' use is virtually none. The upside is that in the future, as
objects may come into the field close enough to couple with the antenna,
or corrosion-weather-"stretch"-age-"or other factors begin to cause
slight imbalances-- the balun steps in and begins enforcing a "balance."

It just seems one would error on the side of caution and use such a
balun. I know of few better examples of a "win-win situation."

Indeed, the article Roy offered seems like one heck of an argument to
this end...

... certainly someone not prepared to weigh the "fly chit" they have
picked out of the pepper should just chuck one in the line and rest
assured "it is a good thing."

Warmest regards,
John

Add that 4 ounces to the weight of 50 feet of coax.
then subtract the weight of 50 feet of balanced line
that is a larger difference

In your original post you said:

"The only thing I have against them (current baluns) is
They are heavy.
and cause the antenna to droop lowering the height of the feedpoint."

Anyway, with say fifty pounds of tension just how much drop are you
talking about? And what difference does it make?

Noticed you have metal straps around the tree trunks.

The QST article of Sept '89 on using trees as antenna supports says,
"Another no-no when attaching an antenna to a tree is wrapping a wire
around the trunk. This strangles the veins in the sapwood the same way
a noose around your neck would strangle you."

Bob, W9DMK wrote:
"The above paragraph was, however, a rather difficult diiffocult to understand ending---."

Fair enough. Ohm`s law prevails at a-c as it does at d-c. That is, I = E / Z, just as I = E / R. If Z is a load impedance, it dictates the current it accepts. An impedance in series with the load affects the voltage applied to the load, but whatever voltage to the load is, the current through the load is related to the voltage adross the load by Ohm`s law.

When a transmission line feeds a load, Ohm`s law prevails at the load Feed a certain current through and it produces a certain voltage drop. Feed a certain voltage and it allows a certain current.

This is repetitious, but it`s true. The line only functions at Zo. The load only functions at its load impedance. The adjustment between these two intransigents are the forward and reverse voltages and currents whose sums make up the actual voltage and current at the load.

Best regards, Richard Harrison, KB5WZI

Reg, I haven't measured it, however...

I am in the process of modeling a balun as follow up on my G5RV feed systems analysis. The scenario is a G5RV at 10m centre height, a vertical drop of open wire line (the so called "matching section") and a balun at near ground height (with unbalanced shunt admittance introduced by the balun to ground).

I have been jiggling the unbalanced shunt admittance introduced by the balun and observing the current through that admittance wrt the feedline currents, and the apparent distortion of the radiation pattern. I could nearly as easily have been comparing the current in one of the wires of the feedline wrt the other, it is just the format of the currents report that makes the former easier. Another interesting observation would be the changes to receive sensitivity to vertically polarised waves (indicating possible feedline pickup).

The models indicate a few things so far:
- the effect of the balun is on the unbalance current distribution on the whole feedline;
- current imbalance at the base of the "matching section" of better than about -15dB caused little distortion of the pattern on 20m and below;
- some configurations seem quite undesirable in terms of pattern distortion even though balun current is quite low;
- raising the antenna / feedline / balun and lengthening the earth connection from the balun shunt admittance changes the current distribution.

This leads me to think that measurement of the imbalance current at a single point might not give the "big picture". I found scenarios where inserting an imperfect balun increased the current at a point (it changed the magnitude of the standing wave and more importantly moved the current minimum), so I could see someone with a handy-dandy current probe measuring such a situation and insisting they have proof the baluns don't "work".

I responded that the load would not accept volts and amps in a ratio which does not fit its load impedance. Perhaps we should reason together some more. The transmission line delivers power to the load at its Zo. When the load impedance is different, there is a surplus of either volts or amps. The surplus nust be reflected because the load can`t take it. That`s all.

No, any tower cannot blow down no matter what. A properly installed tower, installed to manufacturer's specs, will withstand at least the wind load specified by the manufacturer.

In my initial reply in which I pointed out that the tower was guyed to one or more trees, I was trying to be nice. Now that others have chimed in, no more nice guy.

That piece of shit will come down on your house, possibly on neighbors' houses, and possibly on a power line. And when it does, this is a little bit of what will happen:
-- your homeowner's insurance company will send out a tower engineer to check the wreckage and will refuse to pay one penny.
-- your neighbors will sue for damages, their insurance companies will send out real tower engineers to inspect, and your homeowner's liability insurance will not pay a penny.
-- the power company will send out their engineers and will charge you to repair the damage to their lines and equipment.
-- you'll be damn lucky if no one is killed or injured when it comes down. And if anyone is, you could be looking at jail time, depending on whether or not your local prosecuting attorney wants to be a badass.

Here is a short list of problems with your tower:
-- not installed any way close to manufacturer's specs
-- mixed parts of different towers; what the hell is a "Sears" tower? Intended for TV antenna use? There is a BIG difference between real towers (Rohn) and make-believe towers.

-- base is a joke; a guyed 50-foot 25G requires 1.5 cubic yards of concrete. You are supporting 75 feet with less than a yard.
-- base is an even bigger joke when you consider that you used a homemade, non-galvanized base plate welded to some odd pieces of pipe buried a couple of feet in the ground. Welds are not cleaned and galvanized -- they will rust and break. Did you ever stop to think why tower parts are hot-dipped galvanized?
-- guyed to trees. Problem is not that the trees will come down, problem is that in a big blow, the trees will sway one way, pulling the guy wires with them, while the tower is swaying in the other direction, thereby popping the guy wires.
-- guyed to power pole. Did you clear this with the local power company first? When they discover what you have done to their pole, you'll need a lawyer and a big bank account.
-- too close to house -- when that thing comes down, it'll take out a big piece of house.
-- no thrust bearing so all the whipping around the mast will do will be absorbed by the rotator. But that's okay, when the tower comes down you can replace the rotator by standing on the ground.
-- did you use high-tensile steel for the mast or another piece of Radio Shack junk?

I'll look for you in QST -- Silent Keys in a couple of months.

--

Bob Lay is a well known designer and author. I appreciate his criticisms and comments as I appreciate those of Cecil, Ian, Richard C., Walter, and others. I make mistakes and typos, but can`t blame the shakes. My problems are fuzzy sight and forgetfulness. I`ve never taught, or written for magazines or books. I`m just a perpetual student. I`ve learned a lot here.

Thank you to all of you who have taught me much. I always read what Reg, Roy, and Wes have to say. They are rich information sources. There are many more great contributors, but I could not begin to name them all.

Some of the conflicts are roll on the floor funny. I thoroughly enjoy them as an observer. Thanks for the memories.

Best regards, Richard Harrison, KB5WZI

Well, Charlie, those trees have withstood mother nature up til now.
Whether or not they are healthy, they now are supporting a 90 foot tower,
in addition to their own wind load. Things are different now.

As far as ANY tower can be blown down.... not really true for a properly
engineered and maintained structure.

What impedance ratio are you interested in? Reason for asking is that
when I was looking for prior art on current baluns I came across a very
interesting 1:1 design that uses two equal length pieces of coax that would
each be less than an eighth of a wavelength long and which has a very wide
bandwidth. I copied the schematic (which has a slight error) and the photo
to a single sheet PDF file if anyone's interested.

... Joe S. was a bit harsh.

However, I have a cousin who is a mucky-muck in the "insurance scam", frankly it is my belief that some of those guys would beat pennies out of widows if it paid enough.

If it were me, I'd see if I couldn't work on the tree thing a bit and set up some steel-galvanized pipes set in a generous block of concrete and perhaps tied to deadmen to make sure the "insurance thieves" did not find a new victim in me...

... I have about the same respect for insurance people as I do for lawyers, since the supreme court decision on confiscation of private property--they now join those ranks--the constitution seems damn clear on the point to me--indeed, I would expect any high school kid with a proper course in american history to make a better decision than they managed--so nothing surprises me--and for that reason I'd always plan for the worse...

Apparently it makes more difference to me than it does to you.
I don't want it digging into the tree branches.
Nothing wrong with your view - its probably a better-informed view than
mine - but I'll still use balanced line and I still think baluns are too
heavy. I'm just hard-headed that way. :-)

Chris:

You do not agree with any of his analysis?

You do not think this is more of an isolation transformer than a balun?
If not, how do you claim a "transmission line" quality/effect to it?

And, you did notice an insertion loss from this "device", didn't you?

John

I ran across an article on choke baluns recently in the 2004 ARRL
handbook. It said (as best as I can recall) that "purists" might
argue for the use of a choke balun for dipoles for the optimum
radiation pattern, but that most dipoles weren't high enough off the
ground to have a "correct" pattern anyway, so their use for optimum
radiation patterns is questionable at best. Keeping RF out of the
shack might be a different story ? I used a coaxial choke balun on my
G5RV but I don't use either a coaxial choke balun or a commercial
balun on either my 40 meter dipole (too heavy, the dipole is
constructed out of 18 Ga wire) or my 30 meter dipole. I was too lazy
to go through all the hassles of either wiring up a PL connector for
the commercial choke balun I have and I didn't want to wind up several
feet of coax for a coaxial balun (weight and sag issues again)

YMMV

Gary

1891. Re: A Single-Core 4:1 Current Balun

Source record: 74257

Tom is absolutely desparate to prove to the world that you cannot under any circumstances make a 4:1 current balun on a single core. So, he tests the single core Guanella balun with the usual test for a current balun (short the outputs to gound one at a time and see if the input return loss changes) knowing fully well that the Guanella 4:1 current balun on a single core will only work with floating loads.

He is now equally desparate to prove that since nobody but he understands transmission line transformers it is impossible for anyone else to understand or apply them. He also fails completely in understanding that the ferrite used in transmission line transformers is to improve the low frequency end by making the transmission line appear longer.

He's truly amazing, and he is mad as hell. He claims that it is absolutely impossible to make a 4:1 current balun on a single core with a pair of 1:1 transformers (of any kind whatsoever), while the Guanelle 4:1 current balun has a pair of 1:1 transformers on a single core right in front of him. He also makes numerous other outrageous claims that defy all manner of electronics theory.

Here are some of his more memorable quotes along with the URLs for the QRP-L archives so you can see that he is not taken out of context, contrary to what he says:

"...it is impossible to build a 4:1 ratio current balun that uses two 1:1 baluns on a single core."

which in the archives at:

http://mailman.qth.net/pipermail/qrp-l/20050612/020884.html

This is a good one:

"It's well established any balun made up of series / parallel transmission lines requires different voltages from the start to finish of each transmission line. "

which in the archives at:

http://mailman.qth.net/pipermail/qrp-l/20050621/021331.html

and the following:

"It is physically impossible to build a transmission line current balun other than 1:1 on a single core when the windings have mutual coupling through the core."

which is in the archives at:

http://mailman.qth.net/pipermail/qrp-l/20050622/021442.html

as well as:

"It's well established any balun made up of series / parallel
transmission lines requires different voltages from the
start to finish of each transmission line. You can find it
in voltage maps of the balun."

which is the archives at:

http://mailman.qth.net/pipermail/qrp-l/20050621/021331.html

and additionally:

"It is quite possible to build any reasonable ratio of
conventional transformer (as long as it is the square of
turns ratio) on a single core. It is quite impossible to
build a current balun of any ratio other than 1:1 using
multiple transmission line transformers on a single core
unless flux leakage between transmission lines is terrible."

which is in the archives at:

http://mailman.qth.net/pipermail/qrp-l/20050622/021408.html

as well as:

"It impossible to build anything but a 1:1 ratio current
balun when multiple transmission line transformers are
placed on a single core. The voltage map shows that, as does
the basic electrical rule of current baluns that all
currents in all windings must sum to zero under all load
balance conditions."

which is in the archives at:

http://mailman.qth.net/pipermail/qrp-l/20050622/021416.html

There is no room for ambiguity here. As you can see, he is making
unsubstantiated claims of "it is impossible" and "it is well established"
that have no basis in fact. The problem here is really that I solved the
problem of the single-core 4:1 current balun and he is mad as hell because
in his world such a thing cannot possibly exist. So, he makes up additional
new electronics theories to prove that everything you know is wrong.

1892. Re: AD5TH Tower Project Completed - Pics Online

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-27 05:13:31 UTC
From: "J. Mc Laughlin" <jcm@power-net.net>
Message-ID: <11bv2l61vm5red4@corp.supernews.com>
Source record: 74258
Cross-posted to: alt.ham-radio.vhf-uhf,rec.radio.amateur.antenna,rec.radio.amateur.dx

Dear Charlie AD5TH:
You have performed a great service by presenting the results of K5HGR's engineering and your work. Its educational value is almost beyond calculation.

In this part of the world one would need to have a licensed professional engineer (PE) sign off on such a structure. Clearly, down your way one has freedom to innovate without concern for issues that we are required to consider.

My goodness. I recently completed a task of a tall tower in a populated area where I had to have design work from the factory's PE, have that work reviewed by a local PE, get permission from the local municipality, have the airport sign off on the height, take soil samples so that a safe foundation could be designed, watch the fabrication of the foundation to make sure that it was done right, and on and on... Course, we do get serious wind up here and it just would not do to kill someone with a tower collapse.

You sure are fortunate not to have all of the things we have to put up with and not even have to worry about wind. Do keep us posted. The whole story has yet to be revealed.

73 Mac N8TT

Chris:

I see. It is interesting reading anyway, thanks.

Warmest regards,
John

1894. Re: A Single-Core 4:1 Current Balun

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-27 05:16:08 UTC
From: Chris Trask <christrask@earthlink.net>
Message-ID: <sYLve.10045$hK3.434@newsread3.news.pas.earthlink.net>
Source record: 74259

It's not a matter of whether I disagree with him or not. It's a matter of him standing on a cybersoapbox and declaring to the world in numerous ways that such a thing cannot work and that only his analysis of how it can and cannot work is valid. He can't deny that he claimed that it was impossible, so now he has to prove that the solution cannot possibly work the way that he knows that it cannot work. Whatever.

Actually, I sort of like all of the visibility he's giving me. More people are learning that I have solved the problem because of him broadcasting it and trying desperately to dismiss it than would ever know if I had just put it on my web page and not said anything. Free advertising.

I also owe it to him for inspiring me to solve the problem. If he hadn't made such outrageous statements on the QRP-L list I might never have bothered to look into the problem and learn that nobody had yet solved it, or at least solved it and made the solution known.

You never know how and when opportunities like this are going to be dropped in your lap. And sometimes they come from the most unexpected places. Trick is in recognizing the opportunity and then solving it.

If people were to listen to him, the problem would never be solved because according to him it is impossible to make such a thing. I've got three of them on my bench right now made three different ways, and they all work just fine despite the fact that he says they can't. The low frequency 3dB point is around 600kHz and the high frequency 3dB point is beyond 500MHz. Not bad for a couple of hours of work and a few spare parts from other projects.

'pizza + great + circle' works well, though.

Chris:

Well, your design certainly started me thinking. So, I began winding...
on a single core--of course...

I am NOT claiming this is unique, but it works better than the design
you presented, at least, ON my sw receiver...

... take a look at it here:
http://blake.prohosting.com/mailguy2/balun2.JPG

Warmest regards,
John

Once you hang the antenna upside down, make yourself a daisywheel, like on the dinner table. Then jack the daisy table upwards until it has all of the weight of the antenna on it. Then you will not have any weight hanging down from the rotor.

Where can a person take a look at this "Channel Master 8 bay bowtie antenna?

Hi Chris,

Now, given that a "transmission line transformer," as distinct from a
conventional transformer built using transmission lines, does not
support flux in the ferrite; how is it that the ferrite makes the line
appear longer?

Second, if this were to occur (through the design of a "transmission
line transformer" that was a voltage BalUn); what is the advantage of
longer lines?

Hi Chris,

If this relates in some way to your published return loss
characteristic, then I have to offer that it is hardly representative
of the best of BalUns to offer. Sevick offers at least half a dozen
with scads less loss and operating flat to within less than a fraction
of a dB.

Now by your tying in an implicit BW from 600KHz to 500MHz, this comes
too close to brightening your teeth and improving your sex life.
Within 3dB? Given your design, and it being voltage based, supporting
flux through currents driving the core, 3dB would be a hell of a dummy
load and hardly a crowning achievement.

Unfortunately, using "balanced" (symmetrical) line doesn't prevent or reduce feedline radiation. It's subject to the same effects as coax. The only difference is where it happens. Conducted common mode current is explained in http://eznec.com/Amateur/Articles/Baluns.pdf. As for current induced by mutual coupling, both types of feedline will have the same amount of induced common mode current, due to the same cause and having the same effect.

It's not the geometry of the feedline that causes or prevents feedline radiation.

This situation lends itself well to modeling, where it's readily illustrated. While it's often difficult to exactly model a given physical setup, modeling allows us to control the variables and clearly see what's happening. We can often apply this knowledge and insight to real situations.

That's a fair point. The sag in a dipole supported only at the ends is very sensitive to the suspended weight in the middle. And if the end supports are trees, the problem can become extreme.

>Nothing wrong with your view - its probably a better-informed view than
>mine - but I'll still use balanced line and I still think baluns are too
>heavy. I'm just hard-headed that way. :-)
>
If sag is a problem, don't use 300 or 450-ohm ladder line. In terms of weight and windage, it is a very bad solution. A much more practical solution is to make your own ultra-lightweight parallel line. The wire can be much thinner than the main antenna, and you can use a spacing of several inches with the absolute minimum number of ultra-lightweight spreaders.

But more important than that, please stop calling it "balanced line". Somehow we have got into the habit of kidding ourselves that parallel-wire line is balanced line. It isn't!

Parallel line does NOT automatically balance itself. It will cheerfully allow unequal currents on the two wires. That's the same as saying it will cheerfully support an unwanted common-mode current (same magnitude and same direction on both wires) in addition to the wanted equal-and-opposite currents.

So parallel line will NOT be balanced line - not until you have done something to MAKE it balanced.

The one best way to create a balanced feedline is to make the layout of the antenna and feedline is completely symmetrical with respect to ground - and that includes the entire run of feedline back to the shack. Unless you have taken the trouble to do that, you WILL have common-mode currents on the line and it WON'T be balanced. The common-mode current may not be large enough to cause a practical problem... but don't ever kid yourself that it isn't there.

Because it's difficult to use a choke balun with parallel-wire line, and because of the weight problem, about the only practical place where you can stop common-mode currents is at ground level. A choke or a link-coupled ATU will force a minimum in the common-mode current at that position; but a quarter-wavelength up the line towards the antenna, it will also force a maximum in the common-mode current (and if the line is long enough, these maxima will repeat every half-wavelength). With parallel-wire feedline, your only defence against that problem is a symmetrical layout.

Hi.

My Butternut HF9V has an unwanted resonance on about 48 MHz with the result that the SWR on 50 MHz is not good.
Does anyone have a method to remove this resonance, so the 50 MHz SWR can be good??

Vy 73 de Gorm / OZ6GH.

Please skip the personal rhetoric, and tell us how you respond to his
two main technical points about your transformer:

1. That it is simply a 2:1 transformer with an isolated primary and
secondary?

2. That it is not a true transmission line transformer, because your
transmission-line windings are not being fed with opposite polarities
across the *same* end?

Exactly. Nothing I wrote was intended to comment adversely on your
quoted paper, it is interesting and relevant... just a pity the
results tables are not 100% legible.

Modeling shows me the risks of single point measurement, and I agree
entirely with your final statement "While it's often difficult to
exactly model a given physical setup, modeling allows us to control
the variables and clearly see what's happening. We can often apply
this knowledge and insight to real situations". A whole lot of insight
can be gained in a very short time.

Chances are that the bearings are created for a right-side up force
and there will be insufficient bearings for upside down operation.

If your attic is like mine, you may consider getting a board to cross
a couple of rafters and mount the rotor on the floor from that.

Good luck.

You may choose to use the balun near the ground where its weight can
be supported and you can use coax to bring in the lead from outside.
The piece of balanced line will give you low loss to the balun and the
loss from the coax will be minimum due to the short length.

Yes, of course. Twisting helps differential coupling (which in most
cases of sound installationwill not be an issue by virtue of the
relatively large distance from any other conductors to the feedline),
but not common mode.

From: W8JI <w8ji@contesting.com>
Message-ID: <1119874390.757705.302360@g44g2000cwa.googlegroups.com>
Source record: 74179

Please don't consider Chris as speaking for me, or accurately presenting everything I said.

We all know how easy it is to lift selective portions of long exchanges and make things sound any way we like.

The original topic was Sevik's 4:1 balun on a single core, where that balun is made up of two 1:1 ratio choke baluns with parallel inputs and series outputs. The imputs are excited in a transmission line mode (differentially) and the outputs in series. The balun cores provide only ground isolation through common mode impedance. I have a similar balun built by MFJ, and it has terrible balance. It actually is an offset voltage voltage balun.

Early on I specifically excluded transformer-type baluns.

I think the problem is Chris thinks we can feed a transmission line end-to-end on a single conductor and contain energy within the line area. As far as I see, there is nothing causing the line to operate in a TEM mode, but it behaves only as a simple 1:1 transformer.

I beleive this is at the root of the poor efficiency and poor SWR bandwidth of Chris' "balun".

The bandwidth problem would be caused because a transmission line in TEM mode would have distributed capacitance cancelling series inductance of the leads, a transformer winding does not. This also gives rise to the distributed capacitance tending to pull the load side to the voltage balance of the source winding, causing a problem with high frequency balance.

The isolation transformer method has the advantage of much better low frequency isolation and allowing a single core, but falls on its face for SWR response, power handling for a given core size, and high frequency balance and common mode isolation.

I think the real argument or disagreement is if the lines in a parallel or coaxial wound primary and secondary like Chris used are in TEM mode, or simply acting as a transformer. My contention is it is a transformer, and those who think any two parallel or concentric conductors when fed start-to-finish or tend-to-end on one conductor forces a TEM mode are not viewing the system correctly.

It will be interesting to see what others think. I have a partial analysis on my web site in a 4:1 balun analysis , and I'll be adding more information to that as time permits.

Please, just the technical facts. I'll speak for myself.

73 Tom

monopole? you are looking at the end of a piece of coax cable that has been trimmed to show the internal structure.

> That`s all.

Another way of saying the same thing:

The mismatched load rejects voltage in the form of Vref and rejects
current in the form of Iref. Thus Vload is the phasor sum of Vfor
and Vref. Iload is the phasor sum of Ifor and Iref. The
result is that (Vfor+Vref)/(Ifor+Iref) = Zload.

If Z0 and Zload are purely resistive and Zload > Z0 then:

Zload = (Vfor+Vref)/(Ifor-Iref)

Vfor and Vref are in phase, Ifor and Iref are 180 deg out of phase,
because we need a higher voltage and a lower current for RL > Z0.

If Z0 and Zload are purely resistive and Zload < Z0 then:

Zload = (Vfor-Vref)/(Ifor+Iref)

Vfor and Vref are 180 deg out of phase, Ifor and Iref are in phase,
because we need a lower voltage and a higher current for RL < Z0.

By the way, the reason I think this issue is important is Sevik claims two transmission line baluns (excited as real transmission lines, not as isolation transformers) makes a good single core current balun. Not only are people doing that for themselves, commercial people (like MFJ) have copied the idea. They then advertise a single corev TL 4:1 balun as a "4:1 current balun" to consumers.

It seems once something gets into print, it is accepted as fact even when incorrect.

I'd like to clarify Sevik used transmission line mode, not transformer mode coupling, in his single core 4:1 current balun. My contention is it is impossible to build a 4:1 current balun on a single core unless it is a primary-secondary isolation transformer, and an isolation transformer would be a very limited performance balun compared to a properly constructed transmission line balun.

Yes But unless lambda is very short it would be a waste of time and a lot of money compared to using the coax for it's intended purpose and an attached antenna made from separate materials.

yes, you can do that. normally you just strip the shield back and leave 1/4 wave of the center conductor exposed. that makes a reasonable 1/2 wave dipole as long as the shield is at least 1/4 wave long. you can also add aluminum foil or fold the shield back for 1/4 wavelength over the insulation for slightly better results.

How is the feedline dressed, paralleling the lower vertical half of the "C",
or extending horizontally and if so how long is the run. Also you didn't
state how close the 1/2 wave section was to the tree but I assume only
inches. Is the tree dead or live and do you notice any loss of radiation on
the shaded side vs. the open side?
tnx

Charlie,

It's very obvious a lot of hard work went into that project, this makes it even harder to face criticism, but don't lose sight of the fact that it's constructive (even though it's deteriorating rapidly.) There really are numerous problems with your installation, and some will inevitably lead to catastrophic failure and potential loss of life.

Be careful around that thing until you can fix it up. In the least, install dedicated anchor points set in a sizeable concrete base, shorten your top mast and get a thrust bearing up there. Put at least 1/3 of your rotatable mast below the bearing.

This is by no means a complete list, but I think the majority of readers will agree it's a good place to start.

Rob

9. no thimbles on the guy wire connections. Wonder how long before those
10. judging by how the loop of guy wire through the turnbuckle is still
fairly round, I'd bet the tension on the guy wires is too slack. Should
have 400 lbs per guy for 3/16" EHS on Rohn 25.
11. no safety wire through the turnbuckles.

At least the loading (antennas) are pretty light.

John,
Yes, that's very nice. A pair of trifilar windings on a single core.
That's a variation of a 1:1 transmission line balun that I found in a
textbook. I've put the schematic and photo in a PDF file on my web page at:

http://www.home.earthlink.net/~christrask/EM1to1Balun.PDF

I'm qite certain that the two dots connecting the outer conductors to the
shield box are in error as in the photo the outer insulating jacket is not
broken. And those connections do not make sense, at least not immediately,
as the voltages and currents at that point are dissimilar. Also, there
should only be the one ground connection at the near end of the second
cable.

Seems to me that you could use this approach to make a nice, inexpensive
and lightwieght balun with just two 4-foot pieces of coax. I would
certainly like someone to try that and let us know how well it works.

Hmm Well considering he is the former AB7SL it wouldnt surprise me this
is
his creation. If you do a net search on good ole charlie you will find
lots of things.

Keep your head down.

> appear longer?
>

The ferrite makes the line look longer by way of it's permeability, but
that's obvious and I think I'm not understanding your question correctly.
Dye and Granberg cover that in their Motorola application notes as well as
in the section on TLTs in their book "Radio Frequency Transistors:
Principles and Practical Applications." They briefly mention in the book
that the coupling takes place in the magnetic material only at low
frequencies. This effectively makes the line(s)look longer as you are no
longer functioning as a TLT but instead as a flux-coupled transformer, and
the line length is now a function of the physical length of the conductors
and the permeability of the material. In practice a thumbnail approximation
is generally:

L' = L x sqrt(u)

>
> Second, if this were to occur (through the design of a "transmission
> line transformer" that was a voltage BalUn); what is the advantage of
> longer lines?
>

It's a matter of what's practical. If you were to use very short lines
along with a high permeability material such as Fair-Rite 73, you may
encouter a region where the lines are too short to couple properly and the
magnetic material is well above the ferroresonance frequency. And even when
you do get into the flux-coupling m&#65533;de, you still need to have sufficient
line in order to obtain decent coupling at lower frequencies. So, you have
to balance the two (line length and magnetic material) in order to obtain a
wideband transformer that has consistent performance over the desired
frequency range.

I hope I've covered everything here adequately.

Whoa, let's reign back here a bit. The test was still for a 200-ohm load, but it was made asymmetric (150-ohms and 50-ohms) in order to accomodate the 50-ohm network analyzer. The 6dB loss is a result of the voltage at the test port being Vin/2, but the voltage at the other output port with the 150-ohm resistor is 3Vin/2, so there is no excessive loss through the balun. In actuality, there is less than 0.1dB of power loss in the prototype that I made. The test was made to determine if the balance was correct.

Unfortunately, I don't have that edition.
Is it four windings?

1---/////////---2
3---/////////---4
5---/////////---6
7---/////////---8

with (1 to 5) and (3 to 7) as the unbalanced input,
(4 to 6) tied together, and (2) and (8) as the balanced
output?

> secondary?
>

No. It is a pair of 1:1 transformers on a single core. I can make it work equally well by making the two transformers on separate cores. I can also make it with a pair of equal length coaxial cables. Both of these realisations defeat his claim that it is a 2:1 transformer. But at the same time, neither of them answer his claim that it is impossible to make a 4:1 current balun on a single core with a pair of 1:1 transformers.

>
> 2. That it is not a true transmission line transformer, because your
> transmission-line windings are not being fed with opposite polarities
> across the *same* end?
>

This isn't even a gray area. We're making a BALUN, in other words a transformer that has an UNbalanced port and a BALanced port, and in this case fully meeting the definition of a current balun. If we were to accept the above statement, then we would have no choice except to conclude that in no circumstances could we make a BALUN with transmission line transformers because in all cases of BALUNs one port is fed unbalanced.

Making transmission line transformers is not difficult, although Tom is making it appear as though it's some sort of great mustery. For a length of transmission line that is sufficiently short with respect to wavelength, meaning less than an eighth of a wavelength in practice, the following rules are observed:

1. The voltage across the one conductor is equal to the voltage of the other conductor, both in magnitude and in phase.

2. The current in the one conductor is equal in magnitude but oppostite in phase to the current in the other conductor.

These basic understandings of transmission line transformers are well established and understood. Gary Breed brought the concept down to the essentials in:

Breed, Gary, "Transmission Line Transformer Basics," Applied Microwave & Wireless, Vol. 10, No. 4, May 1998, p. 60.

It all comes down to a difference between what is known by way of
established theory and practice versus trying to convince people that
everything we know is wrong.

Chris:

Well, I certainly can see that your claim it is two 1:1 baluns on a single core is technically accurate--the primaries are in parallel and their secondaries are in series... that seems clear enough that it cannot be argued. I can't imagine all NOT to be in agreement on this point.

However, with no electrical connection (transmission line) existing between primary/secondary, and the voltage and current only conducted between these windings by a magnetic flux--I CAN'T see how a "true" balun can be argued, clearly--as opposed to "rf transformer."

But, I am giving this thought--as I am sure are others... I never thought about the humble "balun"/"rf transformer" in some of these ways before--possibly I am not alone... either and anyway, I enjoy the thinking you have established here...

Hi Chris,

You state you have several of these units, performing back-to-back
applications would resolve what you call asymmetry.

>The 6dB loss is a result of the

Where did the 6dB come from? I didn't notice this mentioned anywhere.

Further, there is a strong 2dB/Octave frequency characteristic that is
not explained as an issue of symmetry.

>voltage at the test port being Vin/2, but the voltage at the other output
>port with the 150-ohm resistor is 3Vin/2, so there is no excessive loss
>through the balun.

I don't know where this Vin/2 comes from. What is this divisor you've
injected into the discussion? As you offer it has no obvious
correlation to frequency, it stands that that same 2dB/Octave roll-off
is part and parcel to the unit's loss.

>In actuality, there is less than 0.1dB of power loss in
>the prototype that I made.

No where in your paper do you show the method to determine this, nor
do you reveal such a figure.

> The test was made to determine if the balance
>was correct.

The word "balance" occurs only once in your paper, and that as an
unsupported declaration. I see no work nor data to offer it as a
conclusion.

Hi Chris,

Conventionally, this is not an asset of BalUns. In fact, employing
permeability risks saturation, and saturation risks catastrophic
failure.

The paragraphs that followed (not quoted here) relate to the operation
of a conventional transformer.

>> Second, if this were to occur (through the design of a "transmission
>> line transformer" that was a voltage BalUn); what is the advantage of
>> longer lines?
> It's a matter of what's practical.

Practical? This does not prove an advantage, it is a non-sequitur.

Most of this presumes a conventional transformer design. Your data
supports the results encountered from a conventional transformer
design. The risks of using a conventional transformer design are
legion. I see nothing that suggests this novel design is superior to
a Transmission Line Transformer (AKA Current BalUn).

If it were a mains or an audio transformer with four identical windings, two primaries in parallel and two secondaries in series, most people wouldn't hesitate to call that a "2:1" (voltage ratio) transformer. You could also choose to call it "a pair of 1:1 transformers on a single core" and that would also be valid, though I don't believe that would be most people's preferred description.

The same output voltages can *also* be obtained by a different method, by appropriately wiring two completely separate 1:1 transformers, but that doesn't affect the way we should think about the transformer on a single core.

Sorry, but it all seems to come down to the definitions of "current
balun" and "transmission line transformer" that one chooses to adopt.
Rather than referencing those definitions, please can you quote them
here, in full?

Ian:

Yes, you inject a VERY GOOD point here--I realize my "definitions" are a bit blurry. And, indeed, scanning the internet suggests there are some others out there suffering the same.

What can we all agree are proper definitions to balun, "rf transformer", etc... I admit I have not ever set up a solid foundation of knowledge here--just used ideas, plans, etc which others have made available... and referred to them by the names given... this leaves me at a loss while I investigate.

Unfortunately, I don't have that edition.
Is it four windings?
1---/////////---2
3---/////////---4
5---/////////---6
7---/////////---8
with (1 to 5) and (3 to 7) as the unbalanced input,
(4 to 6) tied together, and (2) and (8) as the balanced
output?

Yes, but they are not windings. They are parallel conductors in pairs.
1 and 3 form one pair. 5 and 7 the other.

You can see a schematic at:

http://www.w8ji.com/balun_single_core_41_analysis.htm

under real transmisison line balun. Sevik proposes the winding can
share a common core.

The entire difference between Chris and I is in my opinion he built what most of the world would call a transformer. There is no forced TEM mode excitation that I can see.

Sevik clearly drew a pair of transmission lines, and that was what I was discussing (and I even exempted a primary/secondary transformer.

If I take a true transmission line choke balun and remove the core, electrical line length does not change significantly. Chris in an earlier post claimed the core lengthened the electrical "line length".

Also I'm assuming he didn't use 100 ohm lines, as a TL 4:1 balun requires. He used coax, which as far as I know isn't easy to make at 100 ohms.

The limited SWR BW, the fact the core affects the electrical length of the "lines", the high loss (.1dB), the fact the lines don't need to be 100 ohm lines, the lack of differential mode excitaion of the start.....all point to operation like any other interleaved winding transformer including audio and some power transformers.

I don't think an isolation transformer is "new art", but calling it a transmission line transformer might be new! ;-)

Hi Gorm,

Is this ground mounted, or mast mounted? Presuming mast mounted, did
you use the suggested radial kit or counterpoise kit? Are they
mounted at the suggested location? Adjusting the length of the 6M
band radial should do it.

Source record: 74125
Cross-posted to: alt.ham-radio.vhf-uhf,rec.radio.amateur.antenna,rec.radio.amateur.dx

Hi Mac,
We had certain constraints to work around such as available guy anchors vs. distance of tower from shack since it is a VHF installation I needed to be as close to the shack as possible for transmission line loss considerations even with 9914. Even though we have over 40 acres the tower needed to be close as hardline was not an option.

I am in the country here so there is little building regulation to adhere to or approvals of construction projects.

We could and still might add concreted guy anchors although they would give more interference for the mower and foot traffic in the back and front yards and that was a concern of the xyl.

The tower has a very low wind load on it with those 2 small lightweight VHF antennas. I know it is very common for hams to overload their "properly engineered and maintained " towers.

As far as mating 2 different brands of towers I was on a budget and had access to 45ft of what has been called "Sears" brand and 40 ft of 25g. We altered our design from an 85ft erection down to 75ft as a safety precaution during and after the installation. Yes trees do sway but as the photos show they don't sway where the guys are attached.

Our insurance man has added the structure to our list of covered items in our policy so evidently it was OK for coverage.
I suppose that no matter how we installed this tower and I so naively posted a photo link there are some that will berate it.

TY for your civility however..seriously it was quite refreshing.....

Still the same charlie. And I dont think I said anything about me
getting a lawyer, Im just relaying what was said to me from a Gentleman
who's name and ham radio callsign was used on USNET to bolster your
comments. Funnything was, he didnt even use the internet. He was very
curious about where it came from and wanted to know where. I pointed
to Cable one to let them tell him.

Funny you disappeard off the internet shortly after that.

Coincidence I guess.

Good luck with that tower of yours. Im sure we will be reading much
more about it some day soon.

Nope, canceled the 1st one, but appearently your ISP doesnt accept
cancels.

If you say Im a novice, then thats your opinion.

Say did you ever learn what headers were and what they can tell you.

Yes one tends to "disappear" off Usenet when they move residences and don't get back online for a year or so. Your powers of reason and deduction leave a lot to be desired. But anyway have a great day and work on that logic processing - OK?

Rick here is a cut and paste from your QRZ page for your callsign of N7HJ
Ricky J Scott
5 77th Pl SW
Everett WA 98203
USA
RickN7HJ@gmail.com

HERE is the snippet....
--
"The only contest I enter is Sweepsteaks (Both CW and SSB) so look for me
there. "

Do you prefer New York Strip or Black Angus Rib Eye?
Besides the logic processing you also need to work on spelling too...how old
are you.. 9?
And don't say it's a TYPO cuz it AIN'T! Like I said always good for a
chuckle....

At least you can spell CW and SSB correctly....how long did those take to
learn Ricky?

Ahhh Standard comeback there Charlie. Dive right to a Typo anywhere
you can find it and try to deflect from the truth.

Nice try.

Dont worry, I wont bother you again, as your still they same ole
charlie.

Just dont start promoting your Affiliate programs again and dont forge
headers again and you will not ever hear from me.

Good luck with your tower, but as a matter of principle, you might want
to save up a bit of rainy day cash for when the Insurance issue pops
up.

Let us know how the Power Company likes your Modification to thier Power Pole. Ours issue tickets for Nails in them. Wonder how a tower harness will go over.

>

I left out the word "current". My balun is a proper current balun as it meets the formal definition, which is that it maintains currents at the output terminals that are equal in magnitude and opposite in phase regardless of potentials at the output terminals with respect to the ground connection on the unbalanced side. You can find this definition in less strict form in the ARRL handbook, such as 1991 pages 16.8-16.9.

The single core Guanella 4:1 current balun meets this definition but only for floating loads. Anything other than that and the two transformers need to be on separate cores.

Source record: 74137

I left out the word "current". My balun is a proper current balun as
it
meets the formal definition, which is that it maintains currents at the

output terminals that are equal in magnitude and opposite in phase
regardless of potentials at the output terminals with respect to the
ground
connection on the unbalanced side. You can find this definition in
less
strict form in the ARRL handbook, such as 1991 pages 16.8-16.9. >>

I agree.It just isn't a transmission line balun, nor an optimum design
for most applications.

The single core Guanella 4:1 current balun meets this definition
but
only for floating loads. Anything other than that and the two
transformers
need to be on separate cores.>>

I agree again. That's what I've been saying all along.

There we have it. Problem solved except for calling transmission lines
transformers, and transformers transmission lines.

That sounds like a good idea, should I mount the antenna's at a 90o
angle relative to each other, with the receiving antenna mounted to
look in the vertical plane (I know where the base station is). And the
transmitting antenna to give as much horizontal plane coverage as
possible, angled down to the areas I wish to receive telephone
coverage? Can I expect good results?

If you need to stay cheap, use good quality RG 6. We used this stuff at 2000 MHz. You can go to the Belden or Times Microwave web site, and find tables that list the loss of various types of coax at common frequencies. BTW, at 900 MHz, RG6 will have less loss than the fat RG8. If you want GOOD stuff, get LMR400, or 9913. DO NOT get RG58/59/8/8X/8FOAM/213/214.

That might depend on what you want to do on 6. Local repeaters? Meteor
Scatter? SSB DX? I use a Cushcraft vertical (R6??), but I don't operate
a whole lot on 6. I have done some Meteor Scatter with it, some SSB, and
some local repeaters. Post what your goals are for 6, and no doubt
you'll get a big response!!

It is ground mounted with 24 buried radials. I have tried with extra
radials cut for 50 MHz. If I make a short over the 18 MHz coil the 48
MHz resonance disappears and the SWR on 50 MHz is perfect. But it
don't work if I detune the coil, short some of the turns or remove the
capacity hat.
I have read on some newsgroups that other have had the same problem,
but I have never seen if they have solved it.

I'm limited to FM simplex since the RT70 only outputs FM and has no
offset that I'm aware of.

1982. Re: A Single-Core 4:1 Current Balun

However, with no electrical connection (transmission line) existing between primary/secondary, and the voltage and current only conducted between these windings by a magnetic flux--I CAN'T see how a "true" balun can be argued, clearly--as opposed to "rf transformer."

But, I am giving this thought--as I am sure are others... I never thought about the humble "balun"/"rf transformer" in some of these ways

before--possibly I am not alone... either and anyway, I enjoy the thinking you have established here... >>>

Aw comen on now John. Every single link coupled transformer from the 1900's to today works on the principle, as do link coupled tuners or matching systems.

Many solid state amplifiers, as amatter of fact MOST HF solid state amps use a primary/secondary transformer to couple unbalanced loads to the PA transistors balanced source.

As a matter of fact many use a similar circuit as this "novel invention". The ALM-500 for example used series secondarys for a period of time, as did Henry amps.

I had a push-pull 810 amplifier that used the same system to drive the grids of the triodes in 1964 or 65.

Using a transformer with interleaved or coaxial windings is about as new as the first power transmission with AC power.

The only thing new or novel about Chris' "invention" is he has redefined transmission line to include flux-coupled windings that do not convey energy via TEM (transverse electiomagnetic) waves like the normal transmission line we use.

Making up a new definition is not the same as producing a new or novel invention. This is almost like the new invention call Fractal antennas or E-H antennas that don't use "old" technology!

Now, this is the IMPORTANT PART and the secret of it's success. YOU MOUNT THE LOWER HORIZONTAL SECTION OF THE LETTER "C" SO THAT IT IS 24 INCHES OFF THE GROUND. This is extremely important because it give is a very low angle or radiation.

I hope you don't believe this.... The *vertical* section provides the low angle of radiation...All you are doing is running a perverted center fed1/2 vertical...

ALSO IMPORTANT. Construct this antenna with the largest gauge of stranded wire you can find. Go to the local hardware store and buy the thickest stranded wire you can get. Or, you can also use 1/8 or 3/8 copper tubing. You want to have as much surface area as possible

I hope you don't believe this either....You could make that out of 18 gauge wire, and likely see little or no difference from copper tube..

I won't comment much on the last two "great" antennas..... Seems to rile people up, when I provide negative feedback on their weapons of choice...

Years ago someone invented something to place on the tops of antennas
that improved their signals considerably. The military allegedly
purchased many of these. They looked like a ball with a tear-drop
shape where the small pointed end fit over the end of the antenna.

Is this that same device or something along it's principal?

Same thing basically...But it ain't gonna improve the signal. At all...
It's not large enough to act as much of a capacity hat.... :(
Might lower received static noise though, compared to a
sharp tip...That would vary also, to the climate, humidity, etc...
Most of my "stinger" whips start out with a small ball...But after
a week, I've usually whacked it off, hitting trees...I don't bother
to replace...

Hi Gorm,

You might try a couple of radials that are above ground level by 20cM
or so and tune them. Your antenna is really designed to be mast
mounted, and it would be better for 6M operation. The reason for this
is that at ground level, 6M is seeing far more clutter from your
house, garage and neighborhood, in its propagation characteristics.

Propagation has nothing to do with the matching problem, but it is a
matter of practical application. With a higher antenna, you can
control the resonances of each band with tuned radials (which are not
tuned so close to, or in ground). With a higher antenna, shorter
wavelengths are impeded less by obstructions.

Dave,

If the discone is rated for 6 meters, go for it. I have talked to people on 6 who were using discones, even though I am horizontally polarized. I would not spend any money on a 6m FM simplex radio.

Ian White wrote,

"Sorry, but it all seems to come down to the definitions of "current balun" and "transmission line transformer" that one chooses to adopt. Rather than referencing those definitions, please can you quote them here, in full?"

I agree. In fact, in thinking about it, I realized that I'm more likely to use the terms "choke balun" and "transformer balun" than current and voltage balun.

Roy's analysis of (1:1 current/choke) baluns, available at http://eznec.com/misc/ibalun.txt, may be interesting reading for lurkers here who may be confused by this thread.

Cheers,
Tom

This thread has got me wondering if "Ruthroff" balun is the
same as "voltage" balun and if "Guanella" balun is the same as
"current" balun, as was explained to me once by a balun guru.

Might try giving us operating parameters.

Are u going to operate repeaters only or skip or both?
For repeaters and mobiles, you'll want vertical polarization. (Cross polarization can be 12dB or more)
For skip, either vertical or horizontal will do.

Can u operate SSB as well as FM - not familiar with the RT-70A ?

A discone has been described as a dummy load in the sky, wide band but no gain.
A vertical 1/4 wave, 1/2 wave, or 5/8 wave will do better. Yagi better still.

Can you get a yagi up 20+ feet with a rotor?

I can't put up a Yagi, so I use a Cushcraft AR-6 Ringo, 1/2 wave vertical
Your results may vary.

Have worked 48 states and 6 DX stations with it using 100 Watts. Brag brag

Have to agree with TAM- but dont expect too much- as a Discone antenna
is a no - gain, ultra wide bandwidth antenna (great for a scanner,
listening to several bands at once, but for signal strength- forget it)!

When six is open, however, all bets are off! Remember many in the '60's
running Heathkit "Sixers" working dx (1/2-1 watt output, and super-regen
reciever)! Tho, would be more effecient with a good yagi, and S.S.B.,
you might be suprised with the results. and remember: 6 meters also
tends to open during the winter solstus , as well as in the
spring/summer times! Good Luck- Jim NN7K

>>>To have the measured SWR change with coax length, means you have
>>>current flowing on the outside of the coax. Your coax then becomes
>>>part of the antenna, so changing its length is changing the antenna
>>>length. This would change the feedpoint impedance and the SWR.

That's correct, except that coax loss will also cause the SWR to change with coax length. Loss will cause the SWR at the antenna (load) to always be greater than at the transmitter (source).

>>>
>>>Unless the line is carrying common mode currents that affect antenna
>>>impedance, changing coax length won't change the SWR, even if the
>>>antenna isn't matched.

Again correct except for overlooking the effect of coax loss.

But there's a real problem in communicating this. If you hook a 50 ohm SWR meter to the input of a 75 ohm, 300 ohm, or line of any impedance other than 50 ohms, the meter reading won't be the SWR on the transmission line. That can mislead people into thinking that the SWR is changing with line length when it actually isn't.

>>
>>********
>>
>>BS
>>
>>Common mode currents on the shield of coaxial cables do not alter the
>>feed impedance. Repeat ofter me. Common mode currents on the shield of
>>coaxial cables do not alter the feed impedance.

Why repeat it if it isn't true? The explanation given by Lancer was correct. If you change the length of the antenna, the feedpoint impedance will change. When you have common mode current flowing on the feedline, the feedline is part of the antenna; changing its length is

changing the antenna's length.

>>
>>The feed impedance of an antenna is solely determined by its physical
>>length and any load impedances within the antenna structure. Load
>>impedances can be stray capacitance with ground via metal objects
>>within the near field of the antenna or even a building.

You have to realize that a radiating feedline (one carrying common mode
current) IS part of the antenna structure.

>>
>>The "Magic" of an electrical halfwave transmission line is at a
>>precise frequency, the reflection of the load to the transmistter is
>>equal to the characteristic impedance of the transmission line
>>irregardless of what impedance it is terminated with.

This is true only of a lossless line. If the load impedance isn't far
from the line's characteristic impedance (i.e., the line's SWR is low),
a small amount of loss won't make much difference. However, if the line
SWR is high, even a small amount of loss can make a major change in the
impedance seen at the line's input. The effect is to skew the impedance
toward the line's Z0.

> Other lengths
>>have the load impedance reflected back and transformed by the length
>>of the coax. The coax then acts as a transformer. It will either step
>>up or step down the impeadnace of the load depending on the load
>>itself and the electrical length of the coax.

It's a little more complicated than that. The line doesn't simply
multiply or divide the impedance by a constant, like a transformer --
except in the special case of a quarter electrical wavelength line or
odd multiples thereof. In other cases, the line does transform the
impedance, but in a complex way in which the resistance and reactance
are transformed by different factors. And reactance can be present at a
line's input even when the load is purely resistive. A Smith chart is a
good visual aid in seeing what happens. Assuming a lossless line, the
impedance traverses a circle around the origin. The radius of the circle
corresponds to the line's SWR. With the chart, you can see all the
combinations of R and X which a given line can produce with a given load
by changing its length. Incidentally, loss causes the impedance to
spiral inward toward the origin as the line gets longer, showing how
loss skews the input impedance toward Z0.

>>
>>All a tuner does is electrically lengthen or shoten the coax by
>>introducing a lumped LC constant that helps present a resistive load
>>to the transmitter. The SWR at the feedline does not change. By
>>placing various different lengths of coax inline, you do the same
>>thing a tuner does, add a lumped LC constant.

As can be seen from the Smith chart, you can produce only particular combinations of R and X by changing the length of a line which has a given load impedance. Unless you're unusually lucky or have planned things carefully, none of these combinations will result in 50 + j0 ohms, the usual goal, at the line's input. In contrast, a tuner is able to adjust both R and X to produce, if designed right for the application, 50 + j0 for a wide range of load impedances.

It requires at least two adjustable components to achieve an impedance match from an arbitrary load impedance, because there are two separate quantities, R and X or impedance magnitude and phase, which have to be adjusted. Changing the line length is only one adjustment, so it can't be guaranteed to provide a match. If you could also change the line's Z0, for example, or the length of a stub, you'd have two adjustments and you could guarantee a match providing you have enough adjustment range.

>>
>>james
>
>
> So thats all my tuner does, lengthen or shorten the coax?
>
> Are you sure about that?

Rest assured, that's not all it does.

In addition, most hams (and other non-professionals -- and even many professionals) don't bother to check that their SWR meter is properly calibrated to the impedance they think it is. Most are nominally 50 ohms, but they can be built for any practical line impedance. Checking calibration is not all that difficult, if you take the time to do it. In addition, your nominally 50 ohm line (or 75 or whatever) can have an actual impedance 10% or more from the nominal value. If you have properly calibrated your meter to 50 ohms, and your line is 60 ohms, you would read 1.2:1 SWR when your line is actually 1:1. And if the SWR on the 60 ohm line is 1.2:1, that 50 ohm SWR meter can read anything between 1:1 and 1.44:1, depending on the line length and its load. Finally, though you may have checked that the meter to reads 1:1 with a 50 ohm load and infinity to 1 with a short or open load, the construction of inexpensive meters may cause them to have significant errors at other load impedances.

The piece that Roy quoted is so outrageous that I can easily believe he
didn't read it right, but I've re-read it several times, and it keeps
coming out the same: the "magical" halfwave line does NOT reflect an
impedance to the source (transmitter) equal to the LINE impedance as
the quoted section says, but it reflects the LOAD impedance (altered by
line loss as Roy says).

...

about tuners, Roy went on to write:

> It requires at least two adjustable components to achieve an impedance
> match from an arbitrary load impedance, because there are two separate
> quantities, R and X or impedance magnitude and phase, which have to be
> adjusted. Changing the line length is only one adjustment, so it can't
> be guaranteed to provide a match. If you could also change the line's
> Z0, for example, or the length of a stub, you'd have two adjustments and
> you could guarantee a match providing you have enough adjustment range.

In addition, two adjustable components in a particular configuration,
even if they are infinitely adjustable (and reasonably close to
lossless!!--a very tall order!) won't necessarily give you the ability
to transform any arbitrary impedance to 50 ohms. There may be whole
practical areas of the complex impedance plane left untransformable.
Also, the efficiency of a particular tuner topology for a given load
impedance may be very good or may be terrible, when using practical
components in the tuner. To reiterate what Roy wrote, it's important
to use the right topology for the job you need to do.

Cheers,
Tom

Wow, I certainly read that (top quote) too quickly. Tom is absolutely
right, as written it's very wrong, and I misread it. I retract my
statement about it's being "true only of a lossless line" -- of course
it's not true at all, but works as Tom says.

Impedance matching of an SWR meter is generally unimportant since most
SWR meters used for HF have a directional coupler that is much shorter
than the operating wavelength. Regardless, I'm not a big fan of SWR
meters -- they are good for detecting a major malfunction but that's
about it. Antenna tuning/matching is best done with a field strength
meter.

Point is that they are usually calibrated for Z0=50 ohms
and are in error when used in Z0 environments differing
from Z0=50 ohms, e.g. Z0=75 ohms.

A local retired instructor of some sort (military, i believe) has the
same opinion. He doesn't like SWR meters but instead measures all his
antennas by field strength meter.

I used to tune my Swan with one. I found when I used an SWR meter,
the minimum SWR dip was NEVER the maximum field strength reading. I
always had to raise the SWR to about 1.3:1 or so.

Around here, most of us know not to mention the performance of an
antenna to him if we only used an SWR meter or antenna analyzer. His
first question is "How did it do with the FSM?"

I believe he is right. Radios drop power when they don't like the SWR
and raise it when it does.

The probable reason for maximum power output not coinciding with the plate current dip is imperfect neutralisation (whether or not the stage is neutralised). If you have a neutralisation adjustment, you can get the two to coincide by properly adjusting the neutralisation.

You can use this coincidence as a quite sensitive indication of optimal neutralisation if you use a digital meter to monitor plate current, and the power out indicator to monitor RF output power. Adjust the tuning and loading for rated power into a dummy load, check the tune cap is peaked for max Po, observe the plate current, carefully dip the plate current, noting whether the dip was left or right of max Po. Now tweak the neutralisation until the two coincide.

When it is all done properly, the "dip" of the plate current should be symmetric, ie it should be as "sharp" approaching from one side as the other. (Asymetric dips are another symptom of non-omptimal neutralisation.

Buck wrote:
>
> Would the changing of the coax lead to moving the SWR meter to a
> different voltage point on the coax?

Sort of, but not exactly. Let's take an example. I'll keep the values purely real to help folks who aren't familiar with complex math, but keep in mind that these are special cases and a full treatment would be somewhat more involved. I'll also make all the transmission lines lossless to simplify things.

An SWR meter really just provides another way of reporting the impedance it sees. You can verify this by connecting pure resistances of various values to its output. For example, a (properly calibrated and operating) 50 ohm SWR meter will report 1:1 if you connect its output to a 50 ohm resistor. If you connect it to either a 25 or 100 ohm resistor, it reports 2:1. It does this despite the fact that there's no transmission line at all connected to its output. Some people can put up a huge smokescreen and waving of hands about reflected waves of one kind or another, but at the end of the day the SWR meter can't tell the difference between a resistor and a transmission line terminated with a load, if the impedances the meter sees are the same. It's sensitive only to impedance; it has no way of knowing even if a transmission line is connected to its output, let alone what the transmission line's SWR or even characteristic impedance is.

Now put a half wavelength piece of 50 ohm coax between the SWR meter and those resistors. The SWR meter will still see the same impedances as before, so it'll report the same SWRs. Now, though, there really is a transmission line connected to its output. And because the meter is a 50 ohm meter and the line has a 50 ohm Z0, the SWR meter reading is the same as the actual SWR on the line. When the load is 50 ohms, the line's SWR is 1:1 and the meter sees 50 ohms so it reports 1:1. When the load is 25 ohms, the line's SWR is 2:1, and the meter sees 25 ohms and reports 2:1. When the load is 100 ohms, the line's SWR is 2:1, and the meter sees 100 ohms and reports 2:1.

Next experiment: Connect the SWR meter through a *quarter* wavelength of 50 ohm line to a 100 ohm load. Now the impedance looking into the line is 25 ohms instead of 100. But the SWR meter reads 2:1 when it sees 25 ohms as well as 100, so it still reads 2:1, which is also still the SWR on the 50 ohm line. You can change the length of the 50 ohm line all you want and, if it's lossless, the line's actual SWR stays the same -- but the impedance at the input end of the line changes. For a 100 ohm load,

when the line is any even number of half wavelengths long, the input Z is 100 ohms. When the line is any odd number of quarter wavelengths long, the input Z is 25 ohms. At other lengths, the impedance is both resistive and reactive, but the line's SWR is always 2:1. And the SWR meter interprets all these possible impedances as 2:1, and that's what it reads. The line SWR doesn't change as you change its length, and the SWR meter reading doesn't change, either.

Now instead of a 50 ohm line, let's connect a half wavelength 100 ohm line to the output of the same 50 ohm SWR meter and hook that to a 50 ohm resistive load. The line's actual SWR is 2:1 and, just like any lossless line, the SWR stays the same regardless of its length. If the transmission line is an even number of half wavelengths long we'll have 50 ohms at the input and the SWR meter will read 1:1, since it's a 50 ohm meter and interprets 50 ohms as 1:1. If we change the line length to a quarter wavelength, the input impedance will be 200 ohms, which the 50 ohm SWR meter will interpret and report as 4:1. So by changing the line length from a half to a quarter wavelength we've changed the SWR meter reading from 1:1 to 4:1, even though the line's actual SWR was 2:1 all along. That's what I was talking about. The SWR meter makes assumptions about the SWR on the line from the impedances it sees. The line transforms the load impedance in a different way than a 50 ohm line would. The SWR meter then assumes an incorrect SWR value for the line, and this incorrect value changes as the line length changes.

The same thing happens if the line has a 50 ohm characteristic impedance and the meter is designed for some other Z0. The lesson is that an SWR meter shows the actual SWR on a transmission line connected to its output only if the SWR meter is designed for the same Z0 as the line.

Too often, people say "The SWR is. . .", but really mean "The SWR meter reading is. . .". As you've seen, the two can often be very different. When you see the SWR reading changing as you change the line length, it doesn't necessarily mean that the line's SWR is actually changing.

Remember, in the preceding discussion I've assumed for simplicity that all lines were lossless. In the real world, no line is, so the actual line SWR will always be higher at the load than the source (unless of course it's 1:1 at the load).

Roy, to cut things short, why don't you just say SWR meters don't measure SWR on anything. All they do is indicate whether or not the transmitter is terminated with its correct load resistance. So they are quite useful.

They won't even tell you what the load resistance actually is unless the load is exactly correct.

Stop fooling and confusing yourselves. The solution to everybody's problems is simple - just change the name of the thing to TLI. (Transmitter Loading Indicator).

And, that comes in TWO parts. ECO6907 and ECO 7213. BOTH wonderful
resources, and both apply to the discussion here. (They DO call them
"conventional transformers" and not Baluns.)

>(Transmitter Loading Indicator).

Or - recalling that what the meter actually measures is the reflection coefficient - why not go back to the old name of "Reflectometer"?

> the impedance at the input end of the line changes. For a 100 ohm load,
> when the line is any even number of half wavelengths long, the input Z
> is 100 ohms. . .

That last sentence should be "For a 100 ohm load, when the line is *any whole number* of half wavelengths long, the input Z is 100 ohms."

Likewise,

> Now instead of a 50 ohm line, let's connect a half wavelength 100 ohm
> line to the output of the same 50 ohm SWR meter and hook that to a 50
> ohm resistive load. The line's actual SWR is 2:1 and, just like any
> lossless line, the SWR stays the same regardless of its length. If the
> transmission line is an even number of half wavelengths long we'll have
> 50 ohms at the input and the SWR meter will read 1:1, since it's a 50
> ohm meter and interprets 50 ohms as 1:1.

"an even number of half wavelengths" should be "any whole number of half wavelengths".

I appreciate the corrections, and encourage anyone who spots errors to bring them to my attention, or the newsgroup's.

Depends on what one is running. My IC-706 folds back
automatically and protects itself. My SGC-500 linear
is advertised to tolerate an SWR of up to 6:1.

That is an incorrect description, though. A discone has zero loss, NOT zero gain. It has ~ unity gain with respect to a 1/2-wave dipole, i.e. ~ 2.15 dBi gain. OTOH a perfect dummy load has infinite loss. Big difference.

A 20K ohms/volt Simpson may yield an irrelevant screen voltage
reading for a pentode because it loads the circuit down. Hand
waving aside, any instrument can be misused.

An SWR meter designed and calibrated for a Z0=50 standing-wave
environment may yield an irrelevant reading when operated outside
of a Z0=50 ohm standing-wave environment.

Trouble is, during steady-state, they only measure the virtual
reflection coefficient which is itself confusing since it is not
the same as the physical reflection coefficient measured by a TDR.

Elaborating, an SWR meter will produce ~ accurate readings for an unknown termination connected to it via a lossless transmission line of any length, as long as that line has the same Zo as the sample section in the SWR meter.

It is only when the transmission line Zo varies from the Zo of the SWR meter line section that accurate measurement of load SWR is problematic.

Selecting line lengths and line impedances to make an SWR meter and/or tx "happy" when connected to an antenna doesn't necessarily mean that the all components in the r-f output system have low SWR. The tx may be able to deliver more power to the net load under those conditions, but SWR may still exist on the transmission line capable of causing its failure.

It does NOT read the reflection coefficient. It reads only half of it. At least half of the information lies in the angle of the RC - which is disregarded, ignored, by the so-called meter.

The magnitude of the RC without its angle is just another worthless number. It can't be used for anything except to calculate a fictional SWR.

Actually, it is pretty useful for a Z0-matched system
since there is one and only one unique solution at the
Z0-match point.

In a Z0-matched system, all forward and reflected voltages
and currents are at the reference zero degrees or at 180
degrees so all the phase angles are known without measuring
them. The physical reflection coefficient is a function of
Z01 and Z02 at a Z0-match point. The sign of the reflection
coefficient corresponds to either zero degrees or 180 degrees
and depends on whether (Z01 < Z02) or (Z01 > Z02).

Since the great majority of amateur radio systems are close
to a Z0-match, this becomes a useful analysis tool for the
most common cases.

just happened upon an App. note written by Philips
Semiconductors (ECO6907) titled "Design of HF wideband power
transformers" which states for both 4:1 and 9:1 transmission
line transformers that they CAN be wound on a single core if
desired for certain conditions (see sections 6.3, 6.4 and 6.6).
http://www.semiconductors.philips.com/acrobat_download/applicationnot...

73,
Larry, W0QE >>

Hi Larry,

Don't fall into the trap of swallowing out of context quotes by Trask.
That's an old tired game, and it only results in everyone chasing their
tails to argue about nothing.

1.) I very specifically excluded primary-secondary type transformers
from the single core current balun statement.

2.) I very specifically was speaking of a dual transmission line 1:1
balun Sevik described using two 1:1 transmission line current baluns on
one core.

If you can think of a way to build a transmission line balun that way
that is a current balun, please let us all know. No one has been able
to do it so far.

Calling a primary-secondary transformer a "transmission line" does not
count, so no "creative" ways to describe something following Lenz's
laws rather than TEM mode is necessary. Everyone already knows a
conventional primary secondary transformer will work.

Well, to be picky all they do is indicate the divergence from the Zo of the meter, in a certain way. If the TX is designed for that Zo then they do what you say, and they're quite useful.

That depends on the radio.

Without SWR protection one with a class C final, like the ones in the little QRP rigs I have lying around, will deliver more power if it sees a lower RF impedance at the final transistor than it was designed for. It will also overheat said final transistor* and possibly damage it. This will happen for some SWR mismatches but not all.

Again without SWR protection one with a class AB or B final, properly tuned for a 50 ohm resistive load, will deliver less power for some mismatches (the same mismatches that would be _higher_ power for the class C final). With other mismatches it would exhibit higher gain but more distortion. At some mismatch and level of drive you could probably expose the finals to too much power dissipation, too high an RF current or too high an RF voltage, and do damage. This depends _heavily_ on the design of the final stage.

With SWR protection, of course, the radio will automatically back off, perhaps even in a way that will do some good.

So I will use an SWR meter to keep the transmitter happy, and a field strength meter to make sure my antenna is doing it's job.

* assuming I got the heatsink design right, neither overly conservative nor overly optimistic.

If you include the possibility of changing the Z0 of the
coax as well as the length, you will be closer to the truth.

This is an illustration of a common problem. It's really improper *impedances* presented to the radio that disturb it; it doesn't know or care about the actual SWR on whatever transmission line may or may not be connected. Transmitters typically specify and show this load impedance as "SWR". But they can't tell the difference between a half wavelength 50 ohm line with 100 ohm load, which has a line SWR of 2:1; any length of 100 ohm line with a 100 ohm load, which has a line SWR of 1:1; a quarter wavelength of 300 ohm line with a 900 ohm load, which has a line SWR of 3:1; or a 100 ohm resistor. All these and an infinite number of other combinations will present 100 ohms to the rig, all will cause the rig's SWR meter to read 2:1, and all will have exactly the same effect.

Only if you are exceeding the power dissapation of the devices.
Considering the way most CBers use radios and amplifiers, your
statement maybe more ture than false.

Generaly if the power disapation of the finals is not exceeded and
there is sufficient margin to handle the reflected power, it will just
dissapate as heat in the output circuits and the fianls. Then this is
only true if the reflection coefficient of the radio is zero. If other
than zero then there will be some of the antenna power reflected back
to the transmitter reflected back to the load. Then the rest is
dissapated as heat. Then you get all kinds of funny things happening
inside the coax. But that is another subject.

Actually can happen if you push the finals to where there is
insufficeint margin to the maximum heat dissapation. Tubes are a bit
more forgiving. Transistor inadequately heatsinked and overdriven,
typical CB usage, often have little of no margin for heat dissapation.

If the transmitter has a refelction coefficient of zero and the load
say .3, then that reflected power from the load is dissapated as heat
in the output circuits and any final transistors or tubes. Now if the
radio has a reflection coefficient other than zero that will lessen
the heat dissapation on the transimiiter. Now you get load and source
reflections convoluting within the transmission line.

You ought to model a 400 Mhz square wave with source and load
refelctions coefficients other than zero. It can get ugly

The point is that the error is insignificant when the directional
coupler is much shorter than the wavelength. The error is even more
insignificant when there are a host of variables and confounds between
the SWR meter and the transmitted field that can (and frequently do)
affect the objective -- field strength. It's much simpler (and just
plain logical) to measure the field strength directly instead of
measuring an abstract value halfway towards the objective and relying
on nothing more than speculation that the rest is working according as
expected.

It is the directional coupler that is balanced for a particular value of Z0.

Nope, that's not the point at all. It is true that a 50 ohm
SWR meter designed for HF may not work on 70 cm but the error
I'm talking about is the calibration error in a 50 ohm SWR meter
designed for HF and used on HF in, for instance, a Z0 = 450 ohm
environment instead of its calibrated-for 50 ohm environment. It
works perfectly in a 50 ohm environment at the HF frequency of
operation. Here's the proof using a 50 ohm SWR meter:

XMTR--1/2WL 450 ohm line--SWR meter--1/2WL 450 ohm line--50 ohm load

The 50 ohm SWR meter will read 1:1, nowhere near the actual SWR

XMTR--1/4WL 450 ohm line--SWR meter--1/4WL 450 ohm line--50 ohm load

The 50 ohm SWR meter will read 81:1, nowhere near the actual SWR

An SWR meter calibrated for 450 ohms will correctly read 9:1
in both cases.

Sometimes yes, sometimes no. If the reflected current arrives out
of phase with the forward current, then the final dissipation can
actually be *reduced* by the mismatch.

Power is power. Phase is not a problem. Take the mafnitude of the
transmitted power and teh magnitude of the reflected power. The
results are phaseless. The magnitudes add linearly.

Frank Gilliland wrote, among other things, "The point is that the error is insignificant when the directional coupler is much shorter than the wavelength."

Certainly "directional couplers" for HF may be built at essentially zero length, and ideally would have exactly zero length, monitoring the current and voltage at a single point on a line. Then SWR or reflection coefficient magnitude or even complex reflection coefficient may be calculated under the assumption we know the desired reference impedance. But if the equipment combines the voltage and current samples in the wrong ratio, you will get the WRONG answer. Even if the coupler looks like a perfect 50 ohms impedance section of transmission line (with some attenuation), the error _in_measurement_output_ can be significant indeed. Just because the coupler looks like a 50 ohm line to the line it's hooked to doesn't mean it will read zero reflection when IT's presented with a 50 ohm load.

And by the way, not everyone who measures and cares very much about SWR (or reflection coefficient) cares a whit about field strength. Not all loads are antennas.

Indeed, as Reg says, we might do better in amateur applications to consider the SWR meter as an indicator of the degree to which we're presenting a transmitter with the desired load. That's really what we're using it for, most of the time. It may ALSO be interesting to know the field strength, but please be aware that a transmitter's distortion products may be significantly higher if it's presented the wrong load impedance, even though the power output may be increased. Field strength alone is not acceptable to me as a means to adjust an antenna load to a transmitter, or as a way to adjust the operating point of the transmitter.

Cheers,
Tom

2050. Top-loaded folded monopole?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-29 22:16:05 UTC
From: Brian <vertfan2@no1net.net>
Message-ID: <F4Fwe.1038$8f7.971@newsread1.news.pas.earthlink.net>
Source record: 74115

Could someone help me analyze my new vertical? It works fine on rx, but I don't want to hurt anything when I actually transmit....

I've seen folded dipoles with short lengths of wire attached to their ends. I guess this is to make up for the velocity factor of the twinlead. Is this really beneficial, or should one just be happy with a somewhat smaller antenna with no wire extensions?

Here's the real question:

I thought I'd try this on my 20 meter folded vertical but found that it worked best when the short length of wire on the end was taped back down the top of the twin-lead rather than extending the overall length of the antenna.

(thanks to everyone here for straightening out the myth about reduced ground losses for folded monopoles btw...)

I borrowed a friends antenna analyzer and with the tail folded back down on the twin lead I was able to get the reactance to zero on some freqs.

Here's the setup:

12 feet of 300-ohm twinlead twisted together at the end
6-inch wire from the end taped back down the top of the twinlead
16.5-foot radials (I can only get two down and NO rf ground indoors)
1/2 wave of RG-58 feedline cut for 20 meters

Some measurements
14.0 R=113 X=0 2.1 swr
14.1 R=87 X=0 1.7 swr
14.25 R=72 X=34 2.0 swr
14.35 R=71 X=53 2.6 swr

I placed some chokes around the feedline and they didn't seem to make any difference.

With the tail extended rather than taped back down the twin-lead the swr was always a bit higher and the reactance would never get below 60 or so.

So is this "taped tail" beneficial or am I fooling myself somewhere?

Thanks!
WN6F

Consider the MRF 140, a 150 Watt 2.0 - 150.0 Mhz N-Channel
linear RF power fet. From the technical data sheet: "100% Tested
For Load Mismatch At All Phase Angles With 30:1 VSWR." You'd have
a tough time damaging this device with a mere 2:1 VSWR.
How do load and source reflections convolute within the
transmission line? That's a new one on me. My old dictionary
defines 'convolute' as "Rolled or folded together with one part
over another; twisted; coiled." The rest of the post is pretty

fanciful, too. A trip to the library would do wonders.

Cecil was talking about current, not power. You can't add
power the way you can voltage and current. If you could, you
could build a very nice perpetual motion machine just by using the
reflections in a transmission line to add power so that the output
was greater than the input.

73,
Larry, W0QE >>

Hi Larry,

Don't fall into the trap of swallowing out of context quotes by Trask.
That's an old tired game, and it only results in everyone chasing
their
tails to argue about nothing.

1.) I very specifically excluded primary-secondary type transformers
from the single core current balun statement.

2.) I very specifically was speaking of a dual transmission line 1:1
balun Sevik described using two 1:1 transmission line current baluns
on
one core.

If you can think of a way to build a transmission line balun that way
that is a current balun, please let us all know. No one has been able
to do it so far.

Calling a primary-secondary transformer a "transmission line" does not
count, so no "creative" ways to describe something following Lenz's
laws rather than TEM mode is necessary. Everyone already knows a
conventional primary secondary transformer will work.

The rig has no way of detecting any alleged "reflected power". It can't tell the difference between a feedline with a lot of "reflected power", a feedline with no "reflected power", and a plain resistor. It behaves exactly the same in all cases, provided only that the impedance that each provides to it is the same.

Anyone not convinced of this should put a couple or more dummy loads in series or parallel, make up a few lengths of transmission line of various impedances, and see for himself.

Roy Lewallen, W7EL

There lies our misperceptions; I was not referring to using an HF SWR
meter designed for coax and plugging it into 450 ohm ladder line.

Tom

The problem is that current is not reflected back from the load, power
is. Thus the you can add magnitudes of power.

Agreed that a rig cannot detect the difference between forward and
reflected power. If the reflection coeffiecient of the source is zero
then final stage of a transmiter will look purely resistive to any
power reflected by the load. Thereby that refelcted power is
dissapated as heat. Other reflection coefficients at the source will
yield lesser amounts of reflected power from the load as heat.

SWR is a ratio, not an absolute value. It doesn't matter if the meter
reads a forward power that's off by 1 or 1000 watts just as long as
the reflected power is in error by the same percent, which will be the
case unless you are using two different meters for forward and
reflected power. Calibrated or not, SWR is the same.

>And by the way, not everyone who measures and cares very much about SWR
>(or reflection coefficient) cares a whit about field strength. Not all
>loads are antennas.

That point might be relevant if this thread were cross-posted to
alt.heaters.induction or rec.dummy-loads.

>Indeed, as Reg says, we might do better in amateur applications to
>consider the SWR meter as an indicator of the degree to which we're
>presenting a transmitter with the desired load.

I agree 100%.

> That's really what
>we're using it for, most of the time.

Unfortunately, it's that "most of the time" part that starts threads
like this. Some radio operators mistakenly think SWR is a measure of
antenna efficiency.

> It may ALSO be interesting to
>know the field strength, but please be aware that a transmitter's

>point of the transmitter.

True story. It's certainly better to use a tunable FSM if one is
available. And such meters are readily available -- any receiver with
a good S-meter.

You need to read _Reflections II, Transmission Lines and Antennas_
by M. Walter Maxwell, W2DU. Even better, get a book on electromagnetics.
You might be able to puzzle some of it out although much of
the math might be too esoteric for you.

In electrical engineering it is the instantaneous power density of two signals passing at the same spot from two directions. That is called Convolution. It also is a nice mathematical means of modeling SWR at any point on a transmisison line at a particular time.

Well if you knew CBers, they are not satidied getting 150 watts from a transistor rated for 150 watts. But in my first paragraph I thought I made it clear but evidently I did not. I guess I must strive to better explain myslef.

Hi James,

No, it is called Superposition, and that is done only with voltage or current. What you are describing may be associated with the Fourier convolution of power series - an entirely different field (and not even additive).

Whats wrong with stating that power is reflected by the load? Isn't
power delivered to the load from the source? Elementary electronics
states that power is voltage time current.

Currents in a transmission line are induced currents. They are induced
from the E and H fields of the TEM wave. I hope that you don't think
that current races up and down the coax millions a times per second?

2068. Radials for a Vertical ?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-30 01:02:02 UTC
From: Gary
Message-ID: <qmg6c1t30ebsrastsm06rcqhnf7m131525@4ax.com>
Source record: 74034

I'm thinking of buying a used Hustler 6BTV vertical (80 thru 10 coverage) and was wondering about how many radials I'd need and how long they should be ? If I do get it, I'd be ground mounting the vertical and planting the radials about 1 - 2 inches deep in soil that's mainly clay.

Thanks in advance.

Okay maybe I am not expressing my self correctly and right now I don't
realy have the time or patience to look back through my old text
books. It has been several years since I have done a lot of RF work
and some things are not as fresh in my mind. It does seem like the
less you use the more you forget or have trouble explaining what you
think.

Most of my work lately has been away from RF.

I've posted many, many times on this topic and have shown a number of cases where the load is perfectly matched but the power dissipated in the source resistor is less than or greater than the "reverse power", clearly demonstrating that this concept is incorrect. There are several examples at Food for thought.txt available at http://eznec.com/misc/food_for_thought/.

Because I've posted so much on the topic I won't do it all again. But I know at least one person on this newsgroup would be glad to have an opportunity to express his views once again. I'll leave this discussion to those who want to revisit it; I don't. But I do want to caution readers that this view of "reflected power" is demonstrably incorrect.

You might want to think about hardware cloth - - half inch screen dipped in zinc - - virtually one continuous sheet, solderable and resistant to weather and moisture. It comes in a 36" width, and I bought about 100 ft of it for my ground-mounted 6-band Butternut. The results have been excellent. People use cars and trailers for their counterpoise - - but this makes a much bigger one, with a lot more capacitance to ground. You can then sod over it or put in plastic sheeting and pebbles - - whatever you like. The only thing you need to settle is to get your sprinklers arranged ahead of time so you don't have to trench through under the hardware cloth.

Convolution is a mathematical stunt you can perform with
two functions: f(x)* g(x) = (integral from 0 to x) f(t)g(x-t) dt.
At least that's how it's explained in Schaum's Outline book
Differential Equations. It's pretty tough to see how it relates
to power in a transmission line. Maybe someone has a use for it
there.

Remember, the high gain antenna will have a narrow beam,
The phone companies have used passive repeaters with good success.

In a word, baloney. The error is independent of length. A zero length
bridge calibrated at 75 ohm is in error when measuring in a 50 ohm
system. Period.

>The error is even more
>insignificant when there are a host of variables and confounds between
>the SWR meter and the transmitted field that can (and frequently do)
>affect the objective -- field strength.

Often, field strength is of zero importance. What do you do when the
device under test isn't supposed to radiate? The simplest example of
this would be a CATV system, yet VSWR is *extremely* important in
cascaded networks.

>It's much simpler (and just
>plain logical) to measure the field strength directly instead of
>measuring an abstract value halfway towards the objective and relying

More baloney and it isn't even sliced.

An easy way to earn and get rich quick
Posted By: joed
Date: thursday, 27 March 2005, at 5:20 p.m.
This is not a scam, I have done it myself!
Can you really earn so easily?
I thought it was impossible. Just read this. I don't even have to convince you that this is
not a scam, because it makes logical sense how you can earn money through paypal.
A little while back, I was browsing through a newsgroup, just like you are now and came
across an article similar to this that said you could make thousands dollars within weeks
with only an initial investment of $6.00! So I thought, "Yeah, right, this must be a scam",
but like most of us, I was curious, so I kept reading :
OPRAH WINFREY and an article published in the Wall Street Journal, here is some of it!!
Everyone has heard about "PayPal" (if you haven't you will soon) and, when I came
across this concept I knew it would work because, as a member of PayPal, I had already
experienced their efficiency and excellent standing. PayPal is the simplest method of making
and receiving payments online anyone has ever seen! Anyone with an email address can join, for FREE! Please read further before you go there...
You can complete this whole process in less than one hour and you will never forget the day
you decided to do so!!! Oh! Did I say FAST? By fast I mean 'the speed of the Internet-type
fast.' Everything is done on the Internet by E-mail. And, if you abide by the rules, it is
NOT considered SPAM, so it's perfectly legal!
Anyway, it said that you send $1.00 through paypal to each of the emails stated in the
article. You then place your own email address in the bottom of the list at No.6, and post
the article in at least 200 newsgroups. (There are thousands) No catch, that was it. So
after thinking it over, and talking to few people first, I thought about trying it. I
figured, what have I got to lose except $6.00, right? Like most of us I was a little

skeptical and a little worried about the legal aspects of it. I found
out that it follows
the same regulations as the mailed chain letters, which according to
the U.S. Post Office
(1-800-725-2161) is indeed legal! Then I invested the measly $6.00.
Well GUESS WHAT!!?.
Within 7 days, I started getting money in my PayPal account! I was
shocked and excited! I
figured it would end soon, but the money just kept coming in. In my
first week, I made about
$25.00.
By the end second week I had made a total over $1,100.00! In the third
week I had over
$9,000.00 and it's still growing. This is now my fourth week and I have
made a total of just
over $22,000.00 and it's still coming in rapidly. Its : Certainly worth
$6.00., I have spent
more than that on the lottery!! : Let me tell you how this works and
most importantly, why
it works? Also, make sure you print a copy of this article NOW, so you
can get the
information off of it as you need it.
REQUIREMENTS: You must have a verified PayPal account. If you do not
have an account you can
go to www.paypal.com and follow the instructions to set up a free
account. In order to place
the initial $6 into your account, you will have to verify your bank
account with PayPal
(which may take a few days). Paypal is 100% secure and is used my
millions of people world
wide.
STEP 1: Send, through PayPal, $1.00 to each email on the below list.
Make the subject of the
payment "Email List" and in the comments, write "PLEASE PUT ME ON YOUR
EMAIL LIST." What you
are doing is creating a service by this and best of all you are not
giving your address to
anyone you do not know.. THIS IS ABSOLUTELY LEGAL!
The email list:
1)arish_n...@rediffmail.com
2)sudip_d...@yahoo.com
3)hoito_tomari_jonno2...@yahoo.com
4)bigmoneygri...@yahoo.com
5)bos...@yahoo.com
6)joed...@itctel.com
STEP 2: Now take the 1st email off the list that you see above, move
the other addresses up
(6 becomes 5, 5 becomes 4, etc?.) and add YOUR email address (the one
used on the paypal
account) as number 6 on the list.

STEP 3: Change anything you need to, but try to keep this article as close to original as
possible. Now, post your amended article to at least 200 newsgroups and message boards. (I
think there are close to 32,000 groups) All you need is 200, but remember, the more you
post, the more money you make - as well as everyone else on the list!
---- DIRECTIONS----
HOW TO POST TO NEWSGROUPS, MESSAGE BOARD----------
Step 1) You do not need to re-type this entire letter to do your own posting. Simply put
your cursor at the beginning of this letter and drag your cursor to the bottom of this
document, and select 'copy' from the edit menu. This will copy the entire letter into the
computer memory.
Step 2) Open a blank 'notepad' file and place your cursor at the top of the blank page. From
the 'edit' menu select 'paste'. This will paste a copy of the letter

$$$$$$ MONEY FAST & SIMPLE @@@@@@@
into notepad so that
you can add your name to the list.
Step 3) save your new notepad file as a .txt file. If you want to do your postings in
different sittings, you'll always have this file to go back to.
Step 4) Use Netscape or Internet explorer and try searching for various newsgroups (on-line
forums, message boards, chat sites, discussions.) Just example you log on any search engine
like, yahoo.com,google.com, altavista.com,excite.com then you search with this subject
millionaire message board? or money making message board? or employment message board? or
money making discussions? or money making forum? or business message board? etc. You will
find thousand & thousand message board. Click one by one then you will find the option post
a new message.
Step 5) Visit these message boards and post this article as a new message by highlighting
the text of this letter and selecting paste from the edit menu. Fill in the Subject, this
will be the header that everyone sees as they scroll through the list of postings in a
particular group, click the post message button.
You're done with your first one!.
Please Be Honest and it will truely work for you: Congrats!

Reply

The word is "blarney". And although the syntax of my statement was
somewhat 'convoluted', the logic is sound -- you can dyno your engine
all day, but the only way to know for sure how fast you can get down
the quarter mile is to run the race.

Strangely enough, the results are not phaseless. The equation
for reflected power at an impedance discontinuity is:

Pref = P3 + P4 - SQRT(P3*P4)cos(theta)

Where theta is the phase angle between V3 and V4, the
associated reflected interferring voltages.

Reference "Optics", by Hecht, Chapter 9 - Interference

The last term in the equation above is known as the "interference"
term. Unless you take the interference term into account, you
don't have a ghost of a chance of ascertaining where the power
goes.

Tom Donaly wrote:
> Cecil was talking about current, not power. You can't add
> power the way you can voltage and current.

That's absolutely correct. When one adds powers, one must
include the interference term which takes care of conservation
of energy. The equation is:

Ptot = P1 + P2 + SQRT(P1*P2)cos(theta)

where theta is the phase angle between V1 (associated with
P1) and V2 (associated with P2). The last term is labeled
the "interference term" and is absolutely necessary when
adding powers. If the interference term is positive, the
interference is constructive. If the interference term is
negative, the interference is destructive.

The best reference on interference and the adding of powers
that I have found is Chapter 9 in "Optics", by Hecht.

Source record: 74050

Gary,
The general 'generic' answer is as many as you can stand to
put in, and as long as you can make them. Usually, the length is a 1/4
wave (or sort of close) for the lowest frequency of use. Don't have
that much room? Then make them as long as possible. The more you put
down the 'better' it'll be. That's where the 'as many as you can stand'
comes in. At some point you'll be ready to quit, so quit...
'Doc

PS - The 'text book' answer? Not really, but probably the average one.

2084. Re: Top-loaded folded monopole?

Dipole means that you have the center of the coax soldered normally to the wire/conduit/tubing that is upward and then the braid is soldered to the radial(s) which are either parallel with the ground, angled toward the ground, or even straight down as if you put a "T" out there and put conduit in (looking at the T as if it were an "E" without the top/bottom legs) and then that attached to a mast pole by the use of a larger "T" or even a 90' el that will fit the mast pole OD

But I specifically stated above the Z0 environment was different
from 50 ohms. The same type of error happens when one uses a
50 ohm SWR meter in a 75 ohm coaxial line.

This is true for a source equipped with a circulator and load but
most ham transmitters are not equipped with a circulator and load.
You must take the phase of the voltages or currents into account
in order to calculate the interference power term. Only then will
you be able to tell where the power goes.

So is your concept of "sloshing" energy. Reflected energy
waves are demonstrably real. One can find out exactly where
the reflected power goes by taking the interference power
terms into account. Optics engineers figured it out a long
time ago.

A 75 ohm bridge is expecting the ratio of voltage to current
to be 75 for a matched system. In a 50 ohm matched system, the
ratio of voltage to current will be 50. Therefore, the 75 ohm
bridge won't be balanced. A 50 ohm bridge would be balanced.

So if I have a perfect voltage source in series with a 50 ohm resistor, and I set the voltage source for 100Vrms (50W to the load, 50W to the source resistor) and I leave the output terminals open (100% reflected power) then the resistor will dissipate 100W? With no current flowing through it?

Wow. I gotta review my basic electronics.

Depends on what you mean by error. Is it a linear system? If the near field strength increases with no change in the radiating structure itself (and propagation is stable, etc.), does the far field not increase by the same ratio? But of course, with a repositionable (rotatable) directional antenna, it's pretty hard to calibrate the FSM in a meaningful way since the antenna system changes (quite a lot, with respect to the FSM) as you rotate it, so you don't know from one time to the next that you have the RIGHT field strength. I'd (ideally) like to know that the transmitter is properly adjusted to output a clean signal, and that the antenna system presents the proper load to the transmitter, AND that the antenna system is radiating like I'd like it to. The "SWR meter" is one component that helps me, but with only one of those tasks. (And yes, it's fine with me if you care also about the SWR on your 450 ohm balanced line...there may also be good reason for wanting to know that.)

Cheers,
Tom

PS--Frank, if you look back in the archives from this group, you'll find directional couplers (of the sort that measure the line at a single point) explained in great detail with four-part harmony and the whole nine yards. Go study them and you may understand why calibration is important.

Regarding errors in the first food_for_thought:

A 100w source equipped with a circulator and load while
looking into an open line, will generate 100w and dissipate
100w in the circulator load. That 100w is definitely not free
power. It can be demonstrated to have made a round trip to
the open end of the feedline and then back to the circulator
load.

The error in your thinking is that the source would see an open
circuit when it is equipped with a circulator and load. It won't.
It will *always* see the Z0 of the feedline as its load (assuming
the circulator load equals Z0). That's the purpose of using
the circulator and load - to allow the source to see a fixed
load equal to Z0.

If that were true then the mere existence of standing waves could
render any measurements worthless. Regardless, I did the experiment a
long time ago -- take a 50 ohm SWR meter and plug it into a 75 ohm
line -- it gives you almost the same measurement (in fact, I didn't
see -any- difference at all). Any small error you might see is, as I
said before, insignificant, especially considering the reason you are
measuring SWR in the first place. The objective is simply to get the
reading as low as practially possible. If you feel the need to quibble
about a couple tenths of a point on a ratio then maybe you're spending
a little too much time playing with the calculator instead of the
antenna.

The bridge is calibrated to the impedance of the directional coupler
(which is usually built to match the expected line impedance, but
cannot be "zero length" in the present state of reality). If the
impedance of the signal is different than what is expected by the
bridge then your power measurements will probably be wrong (to what
extent they are wrong may or may not be important). But if that's the
case then any error will be the same by percentage and sign for both
forward =AND= reflected power because the impedance of the signal is
the same for both forward and reflected power. IOW, the ratio is the
same -despite- the impedance.

If you don't believe me, try it yourself.

Lets make an assumption that we are talking about lossless lines. (If
you are not, then the reflectometer does not provide an accurate
indication of forward and reverse power.)

If you use an ideal 50 ohm reflectometer (that means it is a
negligibly short 50 ohm through line and it is nulled to show zero
reflected power when connected to a 50+j0 load) to measure conditions
in a line, the power flow at that point is the indicated Pf-Pr. If you
had placed an ideal 75 ohm instrument in that spot, the readings are
not necessarily in the same ratio (they are unlikely to be so), but
the difference between Pf and Pr will be the same.

The only other inference you can make from one instrument with regard
to the other will be if one of the instruments shows zero reflected
power, then you know the VSWR that the other instrument will indicate.

Real instruments aren't of zero length, but some types of design are
so close to it at low HF frequencies, you will not detect the error
that is introduced.

The direction coupler samples voltage across and current through a given point. There is always a current transformer of some type and a voltage sample through some type of divider. The "voltages" representing E and I are summed before detection (conversion to dc).

The "directivity" comes because the current phase sample is reversed 180 degrees from the summing phase, causing voltages to subtract.

This means the directional coupler is calibrated for a certain ratio of voltage and current, so when they exist you have twice the voltage in the direction where E and I add, and zero voltage where they subtract.

If the
> impedance of the signal is different than what is expected by the
> bridge then your power measurements will probably be wrong (to what

?What does that mean?

If the directional coupler is calibrated at 50 ohms and you use it in a 75 ohm system you won't get a total reflected null even if the 75 ohm line has a 1:1 SWR. But if you subtract reflected power from forward power readings you will get the correct power, within linearity and calibration limits of the "meter system". This has nothing to do with standing waves. It has only to do with the relationship between current and voltage at the point where the directional coupler is inserted.

I'm not sure if you are saying that or not.

From: Dan Richardson <k6mhe>
Message-ID: <67p7c1ppcdm5piv42018h3qekfbt7bp339@4ax.com>
Source record: 74069

There has been considerable discussion on the antenna news group regarding ground systems for monopole antennas. Invariably, a reference is made to a study prepared by Brown, Lewis, and Epstien that was published in the proceedings of the IRE in 1937. Unfortunately, many amateurs do not live near a major library or university where they would be able to obtain a copy of this paper.

Therefore, I have placed on my web site a scanned copy of "Ground Systems As A Factor In Antenna Efficiency" by G.H. Brown, R.F. Lewis and J. Epstein which was publish by Institute of Radio Engineers in June 1937. This scanned copy is identical in format as a copy I obtained from the library.

Be advised that you need Adobe Reader for viewing. Additionally, this is a rather large file (about 3MB).

You may view this document at:

http://users.adelphia.net/~k6mhe/BLE.html

Please run it again in the following configuration:

Xmtr--1/4WL 75 ohm line--SWR meter--1/4WL 75 ohm line--50 ohm load

The SWR meter will read 2.25:1 when the actual SWR is 1.5:1

Xmtr--1/2WL 75 ohm line--SWR meter--1/2WL 75 ohm line--50 ohm load

The SWR meter will read 1:1 when the actual SWR is 1.5:1

The error is NOT the same percentage. In a matched 50 ohm system,
the 75 ohm bridge reflected power reading will be off by an
infinite percentage, i.e. division by zero.

> If you don't believe me, try it yourself.

I have tried it and you are wrong. Maybe you should try it.

The error that we are talking about has nothing to do with
the length of the directional coupler.

The error that we are talking about has everything to do
with an infinite error in the measurement of reflected power.
Infinite errors are hard to sweep under the rug.

Much noise has been radiated. I speculate that a reminder about what linearity means might get things back on track. In a linear network (lumped or distributed) superposition (of linear signals) produces correct results.

The last statement works in both directions. (The degree to which a network is linear is the same as the degree to which superposition is valid.) (If one supplies a large enough signal to any network, it will become non-linear - as in letting-out-the-smoke-put-in-at-the-factory.)

The catch in all of the above is that superposition only applies to linear signals and power (however indicated) is not a linear signal. Power, which could be complex power S = V*I* (the phasor voltage time the conjugate of the phasor current) or the magnitude of S (apparent power) or the real part of S ("real" power), simply does not obey superposition even in a network that is linear.

Bottom line: assuming the use of networks (lumped or distributed) that are essentially linear, one is only allowed to combine phasor voltages or phasor currents (but not their product nor the square of such linear signals). Once combined, the resultant voltage and the resultant current may be used to find a measure of power. (The "combined" mentioned must be a linear, additive process.)

It seems to me that Roy, and others, have plowed this ground many times.

Power can certainly be combined, just not superposed. Here is
the irradiance equation from _Optics_, by Hecht.

Itot = I1 + I2 + Sqrt(I1*I2)cos(theta)

Irradiance is power/unit-area. The last term is known as the
"interference" term. Hecht provides separate chapters for
interference and superposition, the best treatment of those
two subjects of which I am aware.

Here is the transmission line forward power equation from Dr.
Best's QST transmission line article.

Ptot = P1 + P2 + Sqrt(P1*P2)cos(theta)

It is virtually identical to the irradiance equation above.
The last term is known to be the "interference" term and
for a Z0-matched system, THETA EQUALS ZERO, so for a Z0-
matched system, a complete analysis can be done using only
the forward and reflected power magnitudes. This is something
I and others have been saying for years and it has been
called "gobbledegook" (sic) by Roy (and worse by others) even
though Roy admits that he doesn't care to understand where the
power goes.

> It seems to me that Roy, and others, have plowed this ground many times.

Yes, and they are still not 100% correct. Roy has said:
'I personally don't have a compulsion to understand where
this power "goes".' Too bad he doesn't have that compulsion
because, with a small amount of mental effort, he surely would
have figured it out before me - if by no other means, simply by
referencing the chapter on EM wave interference in _Optics_.

Frank wrote, "Prove it."

OK, here I am at the track (the bench). I have an SWR meter that I've verified with my HP8653 to behave like a short section of 50 ohm line at the frequency of interest. I put a load on its output that I've also verified to be 50 ohms at the frequency of interest. I've applied power to the load through the SWR meter. The indicated SWR is 1.23:1.

I took the SWR meter apart, and located a particular resistor. I changed its value slightly. I re-verified that the meter still looks like a short section of 50 ohm line. I re-ran the experiment of applying power through the meter to the load. The indicated SWR is now 1.05:1.

Yes, I really have done that!

This particular meter is built, as very many of them are, to sample current and voltage at a point of essentially zero length on the line. The current sample (through a current transformer: line center passes through a toroid; secondary is several turns, loaded by that calibration resistor) is converted to a voltage by dropping it through a resistance, and by changing that resistance, I can change the relative amount the current contributes to the measurement. In other words, if the voltage sample is v(samp)=k*v(line), I want to adjust the current sampling so v(i(samp)) = k*Zo*i(line), where Zo is the impedance to which the meter is calibrated to measure SWR. In some meters, there is a means to adjust the voltage sampling ratio easily with a variable trimmer capacitor. Either way works. The adjustment DOES have a TINY effect on the impedance the meter presents to the line it's in, but that is very minor, compared with the range of adjustment of the impedance calibration value.

Yes, I really have adjusted a meter which uses the variable capacitor, too.

Cheers,
Tom

According to this formula, for two laser beams of 100W each, without
any phase difference, we can illuminate a target with
Itot = 100 + 100+ Sqrt(100*100)cos(0)
Itot = 300W

Every CBer's dream....

Hecht should sue you for copyright Unfair Use.

2116. "Food for thought: Forward and reverse power" comments

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-30 16:05:57 UTC
From: Cecil Moore <w5dxp@hotmail.com>
Message-ID: <42c4197b$1_1@spool9-west.superfeed.net>
Source record: 73981

The complete text referenced here can be accessed at:

http://eznec.com/misc/food_for_thought/

The first one is "Forward and reverse power" and is much
easier to read if it is copied-and-pasted into Word.

The first comment is just a nit: "(the current isn't
transformed by the half wavelength line either.)"

A 1/2 wavelength of transmission line reverses the
phase of the current, certainly a 180 degree
"transformation".

The main point centers around this false statement:
"While the nature of the voltage and current waves when
encountering an impedance discontinuity is well understood,
we're lacking a model of what happens to this "reverse power"
we've calculated."

Absolutely false! We are not lacking a model. We have time-
tested models that people with closed minds simply refuse to
consider. One such model is the s-parameter analysis presented
in HP's App Note 95-1, available on the web. Quoting: "Another
advantage of s-parameters springs from the simple relationship
between the variables a1, a2, b1, and b2, and various *POWER
WAVES*. ... s-parameters are simply related to power gain and
mismatch loss, quantities which are often of more interest
than the corresponding voltage functions." (emphasis mine)

The model is there. Concrete brains refuse to take a look
and instead call it "gobbledegook" (sic).

There's another model that agrees 100% with an s-parameter
analysis and it is from the field of optics, covered in
detail in _Optics_, by Hecht. Non-glare glass works the same
way as a 1/4WL matching section in a transmission line.
Again the model is there, just ignored by gurus on this
newsgroup which leads to demonstrably wrong conclusions
on their parts.

What happens to the energy in EM light waves
has been known and understood for many decades and cannot
be understood without an understanding of the laws of physics
governing interference between EM waves. Likewise, what happens
to the energy in EM RF waves cannot be understood without an
understanding of those same laws of physics.

There are many posters to r.r.a.a who have no clue about the
laws of physics governing interference between EM waves. That
ignorance is the entire problem with this discussion. Solution:
Alleviate the ignorance.

Quoting again from Roy's web page:
'ANY MODEL PRESENTED TO ACCOUNT FOR WHAT HAPPENS TO "FORWARD" AND
"REVERSE" POWER AT TRANSMISSION LINE ENDS HAD BETTER GIVE RESULTS THAT
AGREE WITH THE ABOVE TABLE.'

And, of course, the two above power/energy models agree exactly with
Roy's table but that doesn't seem to matter one iota. They are still
"gobbledegook" (still sic).

In the old Heathkit SWR meter were instructions to
install either two 50 ohm resistors for a 50 ohm SWR
meter or two 75 ohm resistors for a 75 ohm SWR meter.
We used a lot of RG-11 back in those days.

>Tom Donaly, KA6RUH
****

Yes Tom

Convultion was the wrong term to use. I made a mistake because i type
as i think and on occasion hit send before i reread what i have
written.

I still contend that a sinusoidal wave travelling down a coax is
comprised of perpendicular(orthogonal) E and H fields. The these
vector fields that induce sinusodial current and voltage potential
vectors in and between the shield and center conductors as the wave
travels. Both the source and reflected waves are comprised of two
vector fields, E and H. Granted this is true only when the load
reflection coefficient is not zero. In that case of zero, then there
is no reflected power.

It is possible to derive from the vector current and vector voltage a
magnitude of those vectors and thus a produce two scalar quantities
that can be pluged into Ohm's Law and derive an instantaineous power
at a given time and position on the coax. That both source and
reflected sinusoidal current and voltage can have derived scalar
values. These values can be directly added.

This all started from an SWR question. I contend that the
instantaineous power at any given time and position of the coax can be
expressed as the sum of the magnitudes or scalar quantities of the
source and reflected powers. If you are wanting just the magnitudes of
the power, then this should work.

james

> Itot = 100 + 100+ Sqrt(100*100)cos(0)
> Itot = 300W

Sorry, I made a mistake in the equation. Please forgive
my omission. Here's the correct equation:

Itot = I1 + I2 + 2*Sqrt(I1*I2)cos(theta)

So if theta equals zero, Itot would be 400w, not 300w.

This is the power of superposition of coherent waves. When
you superpose two 100w coherent laser beams, the resultant
power is indeed 400w and must be supplied by the sources
or supplied by destructive interference from somewhere else.
This is all explained in _Optics_, by Hecht. Hows about
reading it so I won't have to explain superposition to you?

It was an example for Jim Kelley to respond to.
He declined to discuss it, nobody else (including you)
responded with any technical content, so the thread
was abandoned. If you have anything technical to
contribute, feel free to fire it up again.

That happens a lot on this newsgroup. When someone
realizes that he is about to be proven wrong in
public, he simply goes away - human nature.

Cecil, you never actually prove anyone wrong,
you just get excited and irrational whenever
anyone disagrees with you. You're confusing the
fear of being proven wrong with just giving
up in disgust at your silly antics.
73,
Tom Donaly, KA6RUH

It would be interesting to find out who, among the
experts on this group, cannot solve this problem
for Vfwd1, Ifwd1, Vref1, Iref1, Vfwd2, Ifwd2,
Vref2, Iref2 including magnitudes and phase
angles.

Given: a Z0-match at an impedance discontinuity in
a transmission line. Source is unknown. Load is
unknown. Lengths of transmission lines are unknown.
Reference phase: Vfwd1 is incident upon the Z0-match
at a reference phase angle of zero degrees.

---50 ohm feedline---+---200 ohm feedline---
Pfwd1=100w--> Pfwd2=156.25w-->
<--Pref1=0w <--Pref2=56.25w

Contrary to what some people assert, is it possible
to calculate the magnitudes and phases of the
above voltages and currents knowing only the
Z0's and the forward and reflected powers?

Note the
following extremely important qualification. The extra power
must come from somewhere, either from the two sources or from
destructive interference. So says Hecht.

When you phasor add 100v to 100v, what V^2/Z0 do you get?

>>and must be supplied by the sources or or supplied by
>>destructive interference from somewhere else.
>
> [Hecht rolling his eyes] So, this means that Hecht's formula only
> works for steady state? :-)

Yep, irradiance is a quantity averaged over time. It is
steady-state by definition, an accumulated effect.

> If both are 100W pulses, and the lasers are off before the target are
> pulse illuminated -um-
> 1.) 100W
> 2.) 200W
> 3.) 400W

You will get interference rings of 400w/unit-area and
rings of 0w/unit-area all averaging out to 200w total.
All this is covered in _Optics_. Please spare us your
ignorance and read the book.

If the sources are incapable of supplying the extra power,
For every P1+P2+2*SQRT(P1*P2), i.e. constructive interference,
there is a P1+P2-2*SQRT(P1*P2), i.e. destructive interference.

> For an angle of incidence of 30ï¿½

The angle of incidence is always 90 degrees. It is drawn that
way because it cannot be drawn in one dimension. This is typical
of physics textbook drawings. An angle of incidence of 30 degrees
is irrelevant to this particular example.

> How much power is reflected from Surface A (first incidence)?

The reflectance is 0.01, so 1%. First incidence 0.01 watts

> How much power is reflected from Surface B (first incidence)?

The reflectance is 0.01, so 1%. First incidence is 0.0099 watts
Steady-state after re-reflection is 0.01010101 watts

> How much power is transmitted through all interfaces?

One watt net to the "load".
The steady-state forward power in the thin film is 1.010101
watts of which 0.010101 is a steady-state internal reflection
from surface B.

Hi Tor,

We've seen the math pencil-whipped both ways now to cover all the
available answers. The devil's in the details that are not found in:
>Itot = I1 + I2 + 2*Sqrt(I1*I2)cos(theta)
not to mention the glaring mistakes of the first posting of this
formula.

This is like quoting Einstein's E = MCï¿½ (anyone with a Xerox can do
that) and not knowing how much energy it takes to get 100 joules of
green illumination out of a bare lightbulb.

So? Superposition works. With a yagi antenna, through superposition you get an EM wave which has larger intensity in certain directions than for a single dipole with the same power. Someone far away can't tell the difference between switching to a yagi and turning on a linear.

What the formula doesn't say is that in any real system, the wave must have a finite extent (not be a infinite plane wave). Then there must be destructive interference in some directions. So there isn't a problem with conservation of energy.

That's nothing new. Why do they call them "waveguides" :)? Jackson has a chapter with all the hairy details.

Then why are some of the "experts" on this newsgroup
protesting it so much? Some don't seem to comprehend
the energy situation associated with superposition of
EM fields.

Already provided as 0.9792W

****

Since you couldn't answer the original question, let's explore how
accurate your answer to your own question was:

>> How much power is reflected from Surface A (first incidence)?
>The reflectance is 0.01, so 1%. First incidence 0.01 watts
depending upon the polarization rï¿½ = 0.9999% and r|| = 0.9999%
Splitting the difference (0.9999%)
0.0100W
or
0.9900W @ 0ï¿½ available at the next interface
>> How much power is reflected from Surface B (first incidence)?
>The reflectance is 0.01, so 1%. First incidence is 0.0099 watts
depending upon the polarization rï¿½ = 0.9998% and r|| = 0.9998%
Splitting the difference (0.9998%)
0.0099W
or
0.9801W @ 0ï¿½ available at the next interface
>> How much power is transmitted through all interfaces?
>One watt net to the "load".

Already provided as 0.9801W

But, hey, what's 2% error in a conservation of energy equation? You can prove anything (especially your absolute proofs) if you simply discard precision. Pons and Fleishman proved cold fusion by throwing away fewer digits than you.

Well, for 1W of light and presuming cancellation (you cannot achieve full cancellation); this leaves 100ï¿½W of light reflected from a non-reflecting layer - which is quite bright.

So, energy is conserved, and there is no such thing as complete cancellation.

By the way, the math is available from:
Hecht, Eugene, Optics, 2nd Ed, Addison Wesley, 1987
or perhaps you should invest in:
Hecht, Eugene, Optics, Schaum's Outline Series, McGraw-Hill ,1975

As Cecil has hinted (42c43383$1_1@spool9-west.superfeed.net), you can also infer that the impedance at the point where you have two sets of Pf,Pr readings is that the impedance (R, X) is one of two values (which can be visualised as the intersection of two circles on a Smith Chart), one only in the cases VSWR1*VSWR2=Zo1/Zo2 (or the inverse) (which can be visualised as the kissing of two circles on a Smith Chart). The latter includes the case above where one or other instruments indicates VSWR=1, but is more exact because one of the circles is infinitely small.

These cases are not reliably of practical value, the conversion of error in the measurements made with each instrument, into error in the estimated R and X at the point could be huge.

So, I "correct" my statement to "The only other inference that you can reasonably reliably make from one instrument with regard to the other will be if one of the instruments shows zero reflected power, then you know R and X, and the VSWR that the other instrument should indicate.

Thanks Cecil.

Richard Clark wrote:
> But, hey, what's 2% error in a conservation of energy equation?

The error is yours. During steady-state, the forward power
in the thin film is 1.0101 watts. 1% of that is 0.0101 watts.
1.0101 - 0.0101 = one watt delivered to the "load". 100%
accuracy is guaranteed because it is a mental conceptual
exercise. To summarize:

Forward power in air is one watt.
Reflected power in air is zero watts.

Forward power in the thin-film is 1.010101010101010101 watts.
Reflected power in the thin-film is 0.10101010101010101 watts.

Power delivered through Surface B is exactly one watt, exactly
the output of the laser. Exactly the difference between the
steady-state forward and reflected power in the thin-film.

> Well, for 1W of light and presuming cancellation (you cannot achieve
> full cancellation)

That's the great thing about a mental conceptual example. Full
cancellation is guaranteed.

> So, energy is conserved, and there is no such thing as complete
> cancellation.

True for real world stuff. False for mental conceptual examples
like the one being discussed.

Hi Tor,

So, do you see by this example what I describe as the devil's in the details? Absolute proof of complete cancellation using referenced math, which is then abstracted to another field to prove imponderables (mental conceptual examples).

And what purpose is served through this prostitution of citations? That thin films completely cancel reflections? - they do not. That optical interfaces exhibit complete transmission? - they do not. What makes the proofs of these unproven phenomenon necessary such as to dismiss the correct answers? Dare we follow the thread of a suspect theory to arrive at other, equally flawed steps along the way?

>The SWR meter will read 1:1 when the actual SWR is 1.5:1

I'm not going to argue this -- either you can play with theory and
speculate about the results, or you can do the experiment yourself,
observe the empirical evidence, and -then- use theory to explain the
results. When you get around to doing the latter give me a holler in
rrcb since I'm done cross posting on this topic.

And BTW, the best location for the directional coupler is at the
feedpoint of the antenna. Barring that, the next best place is at the
transmitter. Regardless of it's location, you should -never- leave the
coupler floating with the coax or you will end up with results like
what you describe above.

2156. 3-M impedance bridge?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-30 21:44:23 UTC
From: Gary Cavie <m0jjh@despammed.com>
Message-ID: <MPG.1d2e780e5d97a93298969a@news.individual.net>
Source record: 74022

Hi,

Does anybody have any experience with the above, as discussed in The Antenna Experimenter's Handbook, by Peter Dodd G3LDO?

I'm planning to build a version, with a 4-channel A-D to take the measurements, and display the results on the PC. A further stage of development will be to add a DDS as the signal source, giving me a PC-based antenna analyser.

Assuming I go down this route, what do people think about using the voltage derived from input power (Ea if you know the circuit) as the reference for the A-D, giving me a proportional figure for the other 4 measurements without having to scale in software? More to the point, has anybody actually played around with this setup, and would like to share tips?

Thanks

Gary, M0JJH

2160. Modeling TL "dielectric" loss

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-30 22:45:08 UTC
From: Owen <owen@no.where>
Message-ID: <scq8c1hj21c4a8ngr1ek05chinkurob2c9@4ax.com>
Source record: 73926

I am trying to reconcile the following in respect of for practical low loss RF transmission lines:

In the RLGC model for Zo and gamma, it is generally accepted a good approximation is that R=c1*f**0.5, G=c2*f, and L and C are constant.

If the term (G+j*2*pi*f*C) can be rearranged as (2*pi*f*C(G/(2*pi*f*C)+j)), and substituting c2*f for G, written as (2*pi*f*C(c2/(2*pi*C)+j)).

If we regard G to be principally the loss in the dielectric , then c2/(2*pi*C) should give us the dielectric loss factor, D, 1/Q, tan(delta), dissipation factor, power factor, whatever you want to call it.

alpha= 0.5*R/NomZo+0.5*G.NomZo
It also seems generally accepted that Matched Line Loss (MLL) can be modeled well by the expression MLL=k1*f**0.5+k2*f.

(Remember that alpha= 0.5*R/NomZo+0.5*G.NomZo)

It follows then that c2=k2/(10*log(e)*Ro), and that (G+j*2*pi*f*C)= 2*pi*f*C(k2/(10*log(e)*Ro)/(2*pi*C)+j) which implies that D is k2/(10*log(e)*Ro)/(2*pi*C).

Problem is, that whilst PE has D somewhere about 2e-5 up to 1GHz, the loss model for RG58CU (PE dielectric) indicates D 2e-3 much much less than would be expected from D of the PE dielectric alone.

Any thoughts. Is there an inconsistency between the explanation that G is principally due to D of the dielectric material, or I have I messed the maths up?

Owen

Yes. One of the baluns in the ARRL Antenna Book uses an extra180-degrees
of 75-ohm coax to drive an element in a 300-ohm balanced antenna from an
unbalanced 75-ohm aource.

Best regards, Richard Harrison, KB5WZI

Mark,

This month's edition of QEX (July/Aug. 2005) has an article addressing your question with a simulation matching your question exactly. Bottom line: put as many radials as long as possible in your yard and don't worry about it. The simulation with 60 1/4 wavelength radials in a 180 degree arc only resulted in a 1.67dB difference in signal strengths from the radial direction to the no radial direction.

73,
Larry, W0QE

A standard in the VHF and up world; it is used in the T-match.

Question - has anyone ever done any analysis or testing of what happens
to a T-match when run off the center frequency of the balun?

Your question is not clear. Are you asking about tee-match performance
or balun performance?

There has been an examination of the balun performance.

"The Half-Wave Balun: theory and application", J Nagle, K4KJ, ham

Sorry, I thought it was clear. The T-match, which has the balun as a
part. The balun was mentioned as the reference point for the center
frequency.

I saw this apparent discrepancy many years ago, and wondered the same thing. I've come to believe that the extra loss is due to the braided shield, not some unknown additional dielectric loss. There's very little quantitative information about that loss mechanism, but from time to time I've come across comments that it can be substantial.

Roy,

I thought about the effects of through braid loss. I guess any loss
that increases proportionately to f will be captured in the loss model
and allocated against k2.

Below are k2 factors for a few cables of interest. The first three use
PE dielectic, and there is a big difference between RG58 and RG213
where the dimesions of the dielectric are quite different. A small
difference between RG213 and RG214 with similar dielectric size, but
214 has double braiding, suggesting that braid loss / leakage may one
of the factors.

Belden 8262 (RG58C/U) 2.95e-10
Belden 8267 (RG213) 8.23e-11
Belden 8268 (RG214) 7.17e-11

The next bunch don't use braid, but use a corrugated solid outer
conductor. Not a dramatic change in k2 considering how much larger
6-50 is compared to 4-50.

LDF4-50 6.15e-12
LDF6-50 4.60e-12

Could the distribution of the electric field intensity in the
dielectric be a factor, will the dielectric exposed to the highest
field intensity dissipate the most power?

I'm running RG-6 out to my 2 meter antenna. I put my cheap RS HF meter inline to see what I'd read. I got my expected 1.5:1. Wattage read 1/2 of what the radio is rated for. It gets out and I'm not worried about it.

Mark,
Good question! There will be ~some~ gain/loss of signal in
various directions. Probably won't be much gain or loss,
just depends on 'other' things (how near the fence, fence made
of wood/metal, and other mysterious things). Wouldn't worry
too much about it, and if it really bothers you, sneak a radial
or two under the fence for a ways. Hide it well and don't get
caught running stuff in your neighbor's yard!

From where did you obtain D 2e-3 for RG 58 ? That's the most likely source of the discrepancy.

Also the highest grade polyethylene is unlikely to be used for the manufacture of RG58.

The only way to investigate is to lay 100 feet on the ground, in the form of a circle, and measure attenuation vs frequency between the ends from 1 MHz to 1 GHz.

I took the figures published by Belden for their 8262 cable at
frequencies from 1MHx to 1Gz (9 points) and did a polynomial
regression to MLL=k1*f**0.5+k2*f, then substituted k2 into the
expression described in my original post.

I didn't measure the losses, and I recognise that Belden might have
smoothed their results by an intermediate regression, but I figure
that they are not going to exaggerate the effect of k2 unnecessarily.

hi james,

Save your money, you can build this one for under $ 10,
even less if you have some 1/2 " pvc and #12 thhn wire
in the shop !

http://www.cebik.com/moxon/6m.html

Moxon for 6m, use it vertical for FM/Repeaters
or horizontal for ssb and cw.

Smaller then a 2 element yagi but almost the same gain !

Source record: 73948

My reference suggests that D for PE is 2e-4, but even at that, the copper loss would be ten times the dielectric loss out to 2GHz, if I figured it right. It could be difficult to accurately determine your k2 with such a small contribution from the dielectric. But there are likely other mechanisms at work...

Roy mentioned the braid. I recall reading a nice article by, I believe, an engineer with Andrew talking about various loss mechanisms in coax due to things like braid and stranded inner conductor and surface smoothness. The article went well beyond the usual theoretical discussion that assumes smooth conductors and perfectly uniform construction. I wish I could locate it again! I thought it was in "RF Design" magazine, but never could find it again there, so perhaps it was in "Electronic Design" or "EDN".

One mechanism to consider is the effects of a non-constant Zo as a function of distance along the line. There are undoubtedly small variations in the manufacturing process. Over a length of line that's many wavelengths long, even small variations make a noticable difference. It's not a dissipative mechanism, per se, but will show up as line attenuation if you put the line on a network analyzer. Small, flexible lines that are guaranteed to a close tolerance on impedance are quite expensive.

I don't claim to have any definitive answers for this one, but hope my comments give you some ideas where to look.

Cheers,
Tom

I didn't realize that was the source of your loss figures. Reg is right, you have to measure it. Another thing I found long ago is that the published specs don't match reality. I recall finding Belden to be conservative with loss, but that sure isn't the case with some others. I just had occasion to very carefully measure the loss of some Davis RF "Bury-Flex" which they specify as having 2.9 dB/100' at 400 MHz. It was 4.1 dB/100' at 400 MHz and extrapolated very nicely to at least 3.5 MHz with a square root rule. (It has a solid aluminum shield under the copper.) So there's some real specsmanship going on out there.

One other thing I did long ago was to check some semi-rigid lines with solid shield and center conductor and PTFE dielectric, against theoretical calculations. As I recall, the agreement was pretty good -- much better than the garden variety coax.

And by the way, you'll see a noticeable difference in loss between RG-58, which has a solid copper center conductor, and RG-58A which is tinned -- as you'd expect.

A friend has just buried a large amount of chicken-wire under the surface of his wife's new horse-schooling area, so it can double as his antenna testing range.

You might at least be able to persuade your neighbor to let you slot in a few radials with a spade.

2187. Antenna Tuner for 20m Dipole - Build

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-01 10:26:27 UTC
From: Kevin & Natalia <sparc_man@hotmail.com>
Message-ID: <42c5265f@news.iconz.co.nz>
Source record: 73953

Hi All,

I have just built a 20m dipole as a temp antenna for home.
I will be driving it with a TS-830 transceiver, which uses valves in the final stage.
I know that I can only use it close to the cut frequency, but want to build a small tuner to allow me to go off the cut slightly.
I only want the tuner to be used on 20m, so I do not need any coil tapings for switching bands, so maybe a couple of caps will do the job.

Look forward to any replies.

Regards

Kevin, ZL1KFM.

Kevin,
Since the 830s uses valves (tubes on this end) no tuner is necessary.
Simply adjust plate and load or tune and load if moving more than 50
Khz.
I never required a tuner with my TS-820S.
Regards,
Jim, K4SQR

You probably won't find many people who would even recognize how to
approach the problem.

But there will be 10X that many who feel free to tell you why they
think the whole thing is nonsense. What do you suppose that syndrome
should be called - "burying one's head in the sand?"

Hi Kevin, feed it with 450 ohm ladder-line. Make the ladder-line
length an integer number of 1/2 wavelengths. Then you can tune
your antenna system to resonance without a tuner by adding one
foot of ladder-line for lower frequency operation and subtracting
one foot for higher frequency operation. Varying the length of
the ladder-line by 0, 1, or 2 feet should cover the entire 20m
band. My resonant frequencies are 0' = 14.34 MHz; 1' = 14.2 MHz;
2' = 14.1 MHz. Of course, it doesn't have to be in one foot
increments. 35 cm increments might be better. :-)

The 830 already has a tuner built into it- the Pi network output circuit.
When you go through the tune/load procedure you are marching the 830's
output to the load. To put another tuner on the output would be redundant.

The ones who assert that it is impossible can't even afford to
try. If they can't solve it, they look ignorant. If they solve
it, they lose the argument about it being impossible to solve.

Incidentally, I made it easier than necessary. Pfwd2 doesn't
have to be given. The joules/sec into a lossless impedance
discontinuity have to equal the joules/sec out so if three
of the above four joules/sec values are known, the fourth
can be calculated.

How about "burying one's head where the sun don't shine"? :-)
(Sorry, the devil made me say that.)

I find it interesting that the people who say they don't
care where the energy goes respond with a gut feeling and

ad hominem attack when anyone mentions the subject. If
physicists can track a single photon, surely we hams can
track the energy in EM waves.

The pi-network tuning range of the TS-850 (I had owned one at one
time) is capable of tuning the entire 20-meter band on your setup.
Don't worry about it.

2201. Rotate TriBand to vertical?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-01 19:26:56 UTC
From: John Ferrell <johnferrell@sprintmail.com>
Message-ID: <el5bc1hseukbfhdrgn1mjf5hlnp5feojue@4ax.com>
Source record: 73966

I have a Cushcraft A3 beam on a crank up/tilt over tower. When I tilt it over, it still requires a ladder to work on it due to the length of the elements.

What I would like to do is to be able to rotate it as though I were trying for vertical polarization before or during the tilt over process. That would bring the antenna to a "flat" attitude for maintenance and storm protection.

Any thoughts? The usual old fashioned Ham parameters apply: Little cost as possible, build as much as I can my self, etc......

BTW, I have several good TV rotators I might use, but none with a hole all the way through!

2202. Re: Brown, Lewis & Epstein

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-01 20:16:47 UTC
From: Walter Maxwell <walt@w2du.com>
Message-ID: <Swhxe.3456$iv3.2526@fe02.lga>
Source record: 73968

(I have tried unsuccessfully to make the tabular data in the msg below come out correctly. I apologize for that and hope you can interpret the data successfully. Walt,W2DU)

Thanks to Richard Harrison, he has supplied us with the renowned Brown, Lewis and Epstein paper, reporting the voluminous and enlightening experimental data concerning the length and number of ground radials required in approaching the condition of perfect ground underneath a vertical radiator. This paper has long been well known and highly respected in the communications engineering community, and since 1938 has become the standard for engineering the radial systems for AM BC stations Worldwide. The FCC requirement for radials in US BC stations is based on data in the BLE paper.

The tragedy here is that BLE paper has gone practically unknown in the amateur community, as witnessed by so many continual questions and incorrect answers concerning the length and number of radials required to achieve the desired performance of our vertical radiators.

So let me present a short, but definitive abstract of the pertinent numbers taken from the paper, that answer some of the pertinent questions correctly.

As a reference on which to base the radiated field strength, the industry standard has traditionally used millivolts per meter to describe field strength. Specifically, the field strength of 194.5 millivolts per meter at one mile, radiated from a quarter-wavelength radiator over perfect ground with 1000 watts input, is the industry standard. In other words, this field strength is the maximum attainable under ideal conditions. The data below, obtained directly from measurements made at 3 MHz by Brown, Lewis and Epstein in 1937, provide definitive answers to those who ask how many radials of what length are necessary to provide a suitable ground plane. When comparing the fields strengths below, remember that 194.5 mv/meter is the field strength obtained with perfect lossless ground.

Number of Field Strength Loss in dB Relative

Radials in mv/meter to Perfect Ground

Length Length

0.4 wl 1/4 wl 1/8 wl 0.4 wl 1/4 wl 1/8 wl

113 192 180 152 0.112 0.673 2.14

60 185 176 150 0.435 0.868 2.26

30 174 162 150 0.967 1.59 2.26

15 158 153 1.81 2.08

2 126 120 118 3.77 4.19 4.39

When reviewing these data, please keep in mind that as the field strength approaches 194.5 mv/meter the effective ground is approaching perfect ground, which means that the conductivity of the ground in which the radials are planted is irrelevant, only the ground external to the radial system is relevant with respect to conductivity.

It should also be kept in mind that the energy in the EM fields surrounding the vertical radiator diminishes with distance from the radiator. Thus the displacement currents entering the ground diminish proportionately with distance. Consequently, there is a distance from the radiator after which the currents become too small to be significant to the conservation of power radiated. This fact determines the maximum length of the radials necessary to reach the point where the law of diminishing returns prevails. The measurements reported in the BLE paper show this distance to be between 0.4 and 0.5 wavelengths. As noted above, this distance is relative to the amount of energy in the displacement currents at this distance from the radiator, and is in no way relevant to any resonant length of the radial. It is well known that radials buried in the ground lose all sense of resonance.

I have read Al Christman's QEX article, and though he mentions radial systems used in AM BC stations, I doubt if he's read Brown, Lewis and Epstein, else I also doubt if he would have made some of the statements that appear in the article

The Brown, Lewis and Epstein paper is a must read for anyone contemplating the installation of radials for a vertical radiator. Fortunately, Richard Harrison has supplied the paper in the thread below 'Brown Lewis and Epstein'.

My post below has also been added to the above mentioned thread. However, I apologize for the problem in making the tabular data come out right--I tried, but was unsuccessful, so I hope you can interpret the data to be useful to you. Now to the mail I posted in the above mentioned thread. Walt,W2DU

Thanks to Richard Harrison, he has supplied us with the renowned Brown, Lewis and Epstein paper, reporting the voluminous and enlightening experimental data concerning the length and number of ground radials required in approaching the condition of perfect ground underneath a vertical radiator. This paper has long been well known and highly respected in the communications engineering community, and since 1938 has become the standard for engineering the radial systems for AM BC stations Worldwide. Well, Fred, it's because it has everything to do with how much of your xmtr power is heating the ground vs how much is being radiated at whatever frequency you're using. We're not even talking about ground wave, it's how much power is radiated, period.

Maybe this will help clarify it. . .

As Walt and Danny said, this is all about efficiency -- the fraction of your applied power that gets used heating the ground. So the ground wave and sky wave are reduced by the same fraction. Just look at those dB values in the right hand column of Walt's summary, and they'll apply to 75 meter sky wave as well as to ground wave.

They won't be exact, of course, since they depend on both ground characteristics (to quite a fair depth) and frequency. But they're as good a set of working values as you'll find.

Roy Lewallen, W7EL

BL&E measured the groundwave field strength generated by a 200 milliwatt carrier 0.3 miles from a vertical radiator. This value was converted to equivalent field for 1 kW of radiated power at a distance of 1 mile. With this technique, and with 113 each 0.412-wave radials, they found that their measured/converted field was less than 0.1124 dB below the theoretical value for it over a perfect ground plane. These results demonstrate that the consideration of ground conductivity during this study over this short path was unnecessary (REG, please note).

And that was for 113 radials. If only a few radials are used, BL&E report that it is pointless to extend them that far.

According to some experts on this newsgroup, a pure
energy analysis is "gobbledegook" (sic) at best and
impossible at worst. One should avoid an energy (power)
analysis at all costs and deal only with voltages and
currents until the very end of the analysis. It is
ridiculous to try to track the energy inside a transmission
line and any attempt to do so is stupid and doomed to failure
because reflected waves of energy don't really exist. Standing
waves have an independent existence all their own and do not
require a forward traveling energy wave and a rearward traveling
energy wave. The extra energy stored in a transmission line with
reflections just "sloshes" around presumably from side to side.
I could continue but hopefully, you get the idea.

Incidentally, Walter Maxwell doesn't seem to have had any trouble
at all tracking energy (power) in _Reflections_I & II.

Ok, that is one of the reasons that I looked at how k2 changed with
size of the LDF series.

I have just had a look at LMR200 wrt LMR1700. (They have an aluminium
tape +braid outer.) I do not know the value of D for the closed cell
foam dielectric that they use. The k2 factor (and therefore G) of the
larger cable is about 50% of the smaller cable, though there is nearly
a 1100% increase in diameter. It seems that of the few cables that I
have looked at that ones with better shielding result in less
variation in k2 (and G) with change in diameter (for Zo and
dielectric remaining constant). That suggests that shielding and loss
effectiveness of the outer conductor is to some extent reflected in G
(proportional to f).

Tom, the D figure I quoted for PE was from the ITT Radio Engineers
Handbook.

G seems not to be solely or principally dependendent on D of the
dielectric in a general sense. It may be with very good lines, but it
doesn't seem to be so with single braided PE insulated coax. It is
clear that using D (even at 2e-4) to calculate G in an RLGC model of
R58C/U will not give a very good fit to published attenuation
characteristics.

Regarding using the published specs, I am trying to glean as much as
is reasonable from the published specs. I note and agree with your
comment Roy about the quality or accuracy of some specs.

Thanks all for the thoughts on possible contributions to G.

Owen

Actually, if you'll take a read of part 2 of the application note ECO6907,
(ECO7213, which I referenced) It specifically states that part 1 was devoted
entirely to the design of *transmission line transformers*, which had the
advantage of the widest possible bandwidth, but several disadvantages as
well. Therefore, part 2 considers the possibility of applying a
conventional transformer if those constraints were undesireable.

Sheeeeeeeeesh!

That would have been a privilege. When with RCA I worked a bit with Matti Siukola, Oded Ben-Dov, Nick Nikolayuk and others at the RCA broadcast antenna design center and test range at Gibbsboro, NJ . Great facility in those days.

Fred, the radials affect only the efficiency of the radiator--power lost in the ground resistance vs power radiated. The take off, or elevation angle is determined by the ground conductivity external to the radial system, the poorer the ground the less power will radiate at low elevation angles. In other words, the better the ground conductivity external to the radial system the lower the elevation angle of the maximum radiation. If the conductivity was perfect at an infinite distance away from the radiator the elevation angle of the maximum radiation lobe would be zero degrees.

Ian,
I wanted to give a more thorough reply to your question earlier, but at
the time a spontaneous reply did not seem to be sufficient. So, I have put
together an extensive tutorial on the subject of the theory, synthesis, and
practical considerations in the design of transmission line transformers
that is a result of over two decades of designing these things as a hands-on
hardware designer:

http://www.home.earthlink.net/~christrask/TraskTLTTutorial.pdf

2233. Re: Radial Pattern For Vertical Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-02 02:16:04 UTC
From: richardharrison@webtv.net
Message-ID: <6043-42C5F8E4-101@storefull-3258.bay.webtv.net>
Source record: 73849

I only wish I had contributed B, L, and E`s findings on antenna radials. My information has always come 2nd hand from its reprinting by Ed Laport in "Radio Antenna Engineering. Ed has formulas to use in choosing your ground system. I can`t find my copy of Ed`s excellent book at the moment. Laport, like Walter, W2DU, is an RCA alumnus and has associated with the famous pioneers. K6JHE did us a favor by posting the original data.

Common sense says that earth closest to a vertical tower gets most of the capacitive current between the tower and the earth. It is important that density of the ground radials be high close to the tower to reduce current in the lossy soil.

I think there is more to it.

The area of a circle around a tower is (pi)(r)(r), where r=distance from the tower. Area grows as the square of the distance from the tower. Assume a unit depth for the earth crust, and cross-section becomes equal to the surface area.

The resistance of a conductor is its resistive coefficient times its length divided by its cross-sectional area.

Total resistance seen by a ground wave traveling away from a tower is an inverse function of the distance from the tower`s highly conducting ground system. The farther from the tower you get, the more cross-aection there is, so the less resistance there is in the earth. This must be in textbooks, but I don`t recall seeing it. I once asked what a-c resistance to use for the earth at 60 Hz, 50 some years ago, in a student problem and was told to use 25 ohms, no matter what the distance through earth was. That`s when I noodled out the above explanation for the earth`s resistance. It should work at r-f too except for skin effect which if I recall causes an increase in resistance proportional to the square root of the frequency. The skin thickness is proportional to the reciprocal of the square root of the frequency.

The point is that high conductivity is only needed very close to the tower for the ground wave. For a sky wave, you need high conductivity at the reflection point for a vertically polarized wave.

Best regards, Richard Harrison, KB5WZI

Hi,

I'd like to ask 3 questions:

1. Is this the main NEC users forum ? I recently tried the NEC mailing list but is didn't seem to be operational.

2. Which modelling programs are considered state of the art in terms of wire antenna modelling ? Is it NEC 4 ?

3. We have been using wire grids to model antennas on structures. When I mentioned this to a non antenna modelling colleague he thought that using a wire grid "could't be right". Now, wire grids provide a representation of a solid surface. These types of questions can be challenging and deserve an answer.

So, which modelling programs are considered state of the art in terms of modelling the infuence of structures on antenna performance ?

Thanks,

Michael.

> proportional to the reciprocal of the square root of the frequency. . .

That's an approximation which is true only for a good conductor. A poor conductor like ground acts like a conductor only up to a particular frequency, above which it acts like a dielectric in which the skin depth stays constant with frequency. Of course, there isn't an abrupt change, but the characteristic transitions from one to the other much like the frequency response of a highpass filter transitions from a fixed rising characteristic to flatten at the break frequency.
Here are the transition frequencies for some common types of ground, where the first number in parentheses is the conductivity in S/m, the second is the relative permittivity (dielectric constant):

Very good (0.0303, 20): 27.2 MHz
Average (0.005, 13): 6.9 MHz
Poor (0.002, 13): 2.8 MHz

For many purposes involving electromagnetics including determining skin depth, the ground acts like a conductor below the transition frequency and like a dielectric above it.

For example, here's the skin depth in feet for average soil at various frequencies:

Freq MHz Skin Depth Ft

0.5 34.2
1 25.1
3.5 15.9
7 13.8
10 13.2
30 12.6
100 12.6

A very good treatment of this can be found in Kraus' _Electromagnetics_.

Cecil, How about a clue. Can we describe the discontinuity as a two port [S] matrix? The squared magnitude of the "s" parameters does relate to power in a two port network -- am I on the right track? I took your hint, in a previous posting, and downloaded HP's 95-1. I thought I had a copy, but it seems to have evaporated. Also noted your Pfwd2 = 156.25 W, and Pref2 = 56.25 W. Is this type of reading not just a peculiarity of thru-line wattmeters. I realize you can compute mag Gamma sub p, and hence gamma sub v. Why doesn't somebody make a MathCAD NG? It would get rid of all this ugly math.

Regards,

Frank

I'm a little late on this as my news service just hiccupped.

Without wading throught the ASCII math, a couple of thoughts.

1. As Tom said, most references give the D of poly as 0.0002,
although the "Handbook of Coaxial Microwave Measurements" by General

Radio gives it as 0.0003.

2. Again, without having followed the derivation, I find the k2 values to be different from those given by the handiwork of Dan, AC6LA, in his XLZIZL.xls workbook or his TLdetails program. Dan used published attenuation values and Excel regression analysis to determine the values of k1 and k2. See:

http://www.qsl.net/ac6la/bestfit.html

3. Also, General Radio says, "alpha(diel) does not depend at all on the dimensions of the line..." This suggests that there should be no difference in k2 between LDF4-50 and LDF6-50. Dan's numbers show that to be the case.

4. Any loss that doesn't follow the sqrt(f) rule (radiation, wire-to-wire resistance of braid?, etc) as you suggest falls into the k2 term.

5. High-quality, high-frequency (microwave) flex cables do away with braid, or at least solder fill it, and use tape-wound shields.

1. Some people here are familiar with NEC, though most seem to use EZNEC.
The NEC mailing list is at http://www.robomod.net/

2. I would sure like to get NEC 4, but it is a bit expensive.

3. Wire grid models can adequately describe solid surfaces, providing NEC's
guidelines for such models are followed.

4.As for state of the art there are at least two FEM programs available.
One is HFSS from www.ansoft.com

Ok, as I posted in another msg, my figure came from the ITT Ref Hbk,
and even at 2e-4, it comes short of being the entire explanation of G
derived from published loss figures. I accept that the ITT book is
much lower than others.

Just Googling, I see Reg's site shows 2e-5,

Dans k2 figures are based on units of MHz and feet, mine are Hz and
metres, and when you allow for the units base, they reconcile to
within 1%.

>http://www.qsl.net/ac6la/bestfit.html
>
>3. Also, General Radio says, "alpha(diel) does not depend at all on
>the dimensions of the line..." This suggests that there should be no
>difference in k2 between LDF4-50 and LDF6-50.

I believe that is true, my derivation is that k2=9.09e-8 * D /vf (for
units of Hz and metres). So, the "leakage" loss depends on D and 1/vf
(or permittivity**0.5), and dimensions don't enter the equation.

What sent me down this track is trying to reconcile this with the
published specs which claim more loss than is explained by the
dielectric.

> Dan's numbers show that
>to be the case.

Dan's figure (in my ZLZIZL) is, like mine, a little lower (25%) for
the larger line. It is the observation that it varies that suggests
there is more to it than D alone.

>

Yes, see my other post regarding the LMR cables which, like the LDF
series, show much less variation in k2 with cable size than moving
from RG58C/U to RG213.

Thanks for the thinking Wes, Owen

But can you solve this:
A frog is in the bottom of a 10-foot well can jump 3 ft, but every time he jumps 3 ft, he slides back down 2 feet.
How many clothespins does the frog need to hang up 10 towels on the clothesline, if the boat can attain a forward speed of 10 mph as he crosses a river which is running at 5 mph, and the SWR on his analyzer is 1.1 to 1 and the voltage drop across the frog's legs is 150 ohms, then what would the tax on a cup of tea cost in China when the frog gets to the top of the well.

sure, go ahead, toss a quantum physics word problem at us

anyway it just depends on what shade of green the frog was to start
with and since quantum physics teaches us that it is highly possible
the frog can be in two places at once, he was already out of the well
before he even began his escape, the number of clothes pins remains
undetermined

Source record: 73869

I think we can do this without removing that part from the problem.
Add the word "cup" after every word "China", and change the word "China" to "china" in the original problem.
Add the word "a" before the word "china" . Then convert every letter to its ascii equivalent and add 13 to each, then replace the characters for the new ascii values, THEN sol\ve the problem given by Cecil in the first place.
I was not aware that tea was a racist word in the context of the Peoples Republic of China.
Do they not tax tea any longer because of that?
Does that mean its racist (or "profiling") to speak of "Sweet Tea" (Iced Tea) and Southerners in the same sentence?

2255. Re: Radial Pattern For Vertical Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-02 10:44:20 UTC
From: "J. Mc Laughlin" <jcm@power-net.net>
Message-ID: <11ccrvqrdeae804@corp.supernews.com>
Source record: 73870

Dear Richard:

Your last paragraph (quoted below) is a good summary. It, or something
like it, should be an introductory paragraph in every vertical's data sheet
and advertisement. Well done.

To have a vertical perform well for the important (for DX) angles
between 2 and 12 degrees (above the horizon) one would like to have a copper
sea starting one or two wavelengths from the antenna. I have worked 10 watt
backpack stations in the UK when they were by the sea side. No hope to do
so when they are inland.

73, Mac N8TT

2256. Re: Modeling TL "dielectric" loss

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-02 11:15:29 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <da5t0hfap1@nwrdmz03.dmz.ncs.ea.ibs-infra.bt.com>
Source record: 73871

The fact is nobody knows the dielectric loss of polyethylene. It is too small to measure samples in a bridge. The materials of which the bridge is made have losses of the same order.

The slightest unavoidable impurities and contamination during production cause wide variations in D.

Coaxial line Attenuation = A*Sqrt(F) + B*F

The most accurate way to estimate D at HF is to measure attenuation versus frequency over a wide frequency range on several miles of solid polyethylene coaxial line.

Then separate the constants A and B by plotting on graph paper Attenuation/Sqrt(F) versus Sqrt(F). and then do a few simple calculations.

I have performed this operation several times during acceptance tests on newly laid cables. The cable insulation was mainly air-spaced with the inner conductor being supported by polyethylene disks at 1.5" intervals.

D can vary noticeably from one length of cable to another manufactured from a different batch of nominally identical materials.

I have also measured attenuation on many miles of 1" diameter solid polyethylene submarine cable and determined quality of the insulation by this graphical means. It is necessary to make attenuation measurements very accurately by the substitution method against standard attenuators.

But for comparison, I have never measured the relative junk used by radio amateurs.

Reg.

> gamma sub v. Why doesn't somebody make a MathCAD NG? It would get rid of
> all this ugly math.

Hi Frank, the point is that the math is not ugly. Simple
math, deductive reasoning, and a four-function calculator
with square root is all one needs.

```
---50 ohm feedline---+---200 ohm feedline---
Pfwd1=100w--> Pfwd2=156.25w-->
<--Pref1=0w <--Pref2=56.25w
```

```
Vfwd1 = SQRT(Pfwd1*Z01) at zero degrees = 70.7v at 0 deg
Ifwd1 = SQRT(Pfwd1/Z01) at zero degrees = 1.4a at 0 deg
(Vfwd1 and Ifwd1 are the reference phase angles.)
Vref1 = 0 (given)
Iref1 = 0 (given)
```

```
Vfwd2 = SQRT(Pfwd2*Z02) at zero degrees = 176.8v at 0 deg
Ifwd2 = SQRT(Pfwd2/Z02) at zero degrees = 0.88a at 0 deg
Vref2 = SQRT(Pref2*Z02) at X degrees = 106v at 180 deg.
Iref2 = SQRT(Pref2/Z02) at Y degrees = 0.53a at 0 deg.
```

```
Note: For a Z0-match to exist:
If Z02 > Z01, then X=180 degrees and Y=0 degrees
If Z02 < Z01, then X=0 degrees and Y=180 degrees
Vfwd2 and Vref2 have to add up to Vfwd1
Ifwd2 and Iref2 have to add up to Ifwd1
```

We didn't even have to calculate rho. This energy analysis
works for all Z0-matched systems, the most common of
amateur radio systems.

_____

Very interesting, Richard, of all the years I've been on this NG you are the first RCA person I've met on the NG. What years were you with RCA?

While at the RCA Princeton Labs I also worked with O.M. (Woody) Woodward, Bruce Rankin, and Don Peterson. Perhaps you knew them. I joined RCA in 1949, transferred to the antenna lab in 1957, and later originated the antenna lab at the then new Astro-Electronics Division in Hightstown. Was located there until I retired to DeLand, Florida in 1980. While at Princeton I developed the entire antenna system for TIROS 1, the World's first weather satellite.

I never had the pleasure of meeting any of the guys at Gibbsboro, but the names of Matti and Oded came up quite often. I heard Woody and Jess Epstein talking with them on the phone quite frequently.

I also spent some time at Cherry Hill as part of a three-man team developing the 3.6 GHz dish used on Lunar Rover, the moon buggy. I performed all the final impedance and antenna pattern measurements on the three dishes prior to delivery to NASA.

Perhaps we can meet some day and discuss our experiences at RCA. I consider myself fortunate to have been there during the early days of space exploration, they were truly exciting days.

Walt, W2DU

2259. Can you solve this 2?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-02 13:21:07 UTC
From: Cecil Moore <w5dxp@hotmail.com>
Message-ID: <42c695c0$1_2@spool9-west.superfeed.net>
Source record: 73874

The first example was much too easy. How about this one?

```
---50 ohm feedline---+---300 ohm feedline---
Pfwd1=100w--> Pfwd2 not given-->
<--Pref1=0w <--Pref2 not given
```

Given a Z0-match at point '+':
Solve for Vfwd1, Ifwd1, Vref1, Iref1, Pfwd2, Vfwd2, Ifwd2,
Pref2, Vref2, Iref2, including magnitudes and phase angles
for all voltages and currents. Source is unknown. Load is
unknown. Lengths of feedlines are unknown.

Who thinks this one is impossible to solve?

1965-1980. My position certainly was not as exalted as that of Epstein/Lewis/Siukola/Maxwell/et al, but I was fortunate enough to work with Siukola and Ben-Dov of Gibbsboro in developing and proving RCA's RF Pulse test equipment system used to evaluate and optimize broadcast TV antenna systems. This test system may be thought of as a "narrow-band TDR," in that it duplicates the spectrum of the standard TV signal, rather than using a bandwidth of maybe 100X that of the TV channel. Excess test bandwidth gives high pulse returns outside the TV channel -- which are valid, but unimportant to the performance of the antenna system.

RF

Source record: 73878

Since the name of Dr. George H. Brown, of Brown, Lewis and Epstein is not well known in the amateur community, I would like to acquaint you with some of his other accomplishments that are well known in the engineering community, especially in the AM-FM-TV broadcast community. His name deserves attention in the amateur community as well.

In addition to his work that established the ground radial standards for AM broadcasting, he discovered the reason the early diamond-shaped tower radiators produced undesirable radiation characteristics, and proved experimentally that towers of uniform cross section solved the problem. As a result of his experimental proof, the FCC denied further use of the diamond shape tower, and has since required all AM BC antenna towers be of uniform cross section. He also developed sectionalized radiators for control of the elevation pattern.

He invented the ground-plane antenna for VHF/UHF use. He found that two radials were sufficient, but marketing people convinced him that the antennas would sell better with four.

With his famous 1937 paper, 'Directional Antennas' he established the basis for directional arrays used in thousands of AM broadcast stations.

He worked closely with John Kraus in the early days, and showed Kraus the importance of close spacing of elements in an array to increase the gain over that obtained with quarter-wave spacing. The result was Kraus' close spaced beam known as the 'W8JK' beam. Kraus gave this credit to Brown in his book, "Antennas."

He developed a method for RF heating, especially for the joining, or 'sewing' of plastic sheet material, a method that led to the development of microwave ovens.

As lead engineer in RCA's color television lab at the RCA Laboratories in Princeton, he successfully led the development of the present system color system used in all US tv operations, the NTSC system that permitted black and white receivers to see color transmissions in black and white, overturning the original FCC acceptance of the CBS spinning wheel system that would not permit black and white receivers to receive color transmissions.

George Brown retired as an Executive Vice President of RCA.

These are just a few of his noteworthy accomplishments as an extraordinary engineer.

Hi Cecil, thanks for the info, I will study your response.
I did not mean that math is ugly, I meant that attempting to format in a

text file is ugly. It would be so nice if what we type on was a MathCAD sheet.

Regards,

Frank

I want to raise the center of my 91 ft folded dipole to at least 35
feet. I live on the west coast of Florida with all the attendant
possibilites of hurricanes. I cannot afford a retractable tower and do
not have room for proper guy wires. I want to be able to put a pulley
at the top so I am able to lower the antenna in the event of high
winds. I have a cement block house with a roof peak of about 16 feet,
I would prefer not to have to pour a base for the "mast".
I would appreciate any advice on supporting the "mast" to the house
wall and what material to use for the "mast" so that it might not be
permanantly bent by 125 mph winds.

Any constructive help gratefully welcomed

I have a Hygain TH3Mk4, which is on a 14 foot boom. What I do is to first rotate the antenna so that when the tower is tilted down, the antenna is pointed straight up, with the reflector parallel to the ground. I tilt the tower until the rotator is resting on the part of an 8 foot step ladder that the paint can is supposed to go on. This gives access to the reflector and driven element. At that point I would take the antenna off the boom if I had to do anything other than work on the feedline, but have had no reason to do that.

Here is something else you could try: drill a hole through the boom, mast, and mounting plate, and insert a 1/4 inch bolt through the whole thing. Now, remove the U bolts that fasten the plate to the mast. You can now swing the boom parallel to the mast. I don't need to do this for the HyGain, but it should work with the CushCraft.

I have worked 10 watt
backpack stations in the UK when they were by the sea side. No hope to
do
so when they are inland.

Three or four weeks ago I drove down to the beach to do
some fishing, bbqing, and general r&r. Of course, I had my
radio. I pulled my truck right up next to the water. Didn't
bother throwing a "water" ground wire out. Just ran normal
with my "extended" 14 ft mobile whip. The coil 8 ft above the
base of the whip. 100w. Was yakking on 40m late at night, and among
all the stations, mostly home stations, some running power,
I was one of the loudest ones on the freq. Can't beat a good
saltwater location. :) Also, a mobile late at night on 40m,
generally is as good as most normal height dipoles, etc. In fact,
I had one guy do a test. He was in the house in FLA, and I wagered
that his signal would increase if he went to his mobile.
He did, and it did. MK

A rat shack pushup pole, *properly* guyed, should do the
trick. I'm not sure about 125 mph winds though. I'm not
sure many would survive that...But... The pushup masts
are retractable. What I do when a hurricane is coming,
is to retract the mast down to it lowest level. That makes
it super strong, and being low, there is little risk. I've
had those masts ride out hurricanes, even all the way up.
But...It wasn't 125 mph though... Maybe 100-105 mph or so...
You can buy the brackets for the house.

I admit I discount the last digit of preceison in the values. As Dan says so well in a note on his web site:

"Caution: The computed values for K1 and K2, like all computed results in both the XLZIZL package and the TLDetails program, are shown with a precision of a few digits beyond what is reasonable in normal engineering practice. This is done to allow you to spot trends and do theoretical studies. Don't allow yourself to become overly concerned with the exact values for K1 and K2. The loss characteristics for any transmission line will vary with manufacturing tolerances, age, bending, exposure to heat and sunlight, and even changes in the ambient temperature. The values used here, and indeed in any modeling package, must be considered as "best guess" estimates of the actual attenuation for any given line."

>
>Yes, see my other post regarding the LMR cables which, like the LDF
>series, show much less variation in k2 with cable size than moving
>from RG58C/U to RG213.

Another cautionary note:

While Dan was working on his programs we corresponded a lot via email. In one instance, he said "X" and I said "Y" about Heliax.

After some fussing around, we learned that my paper Andrew catalog no. 35 has different loss figures for the LDF series than does the "new" online catalog no. 38. As we would say in America, like trying to shoot at a moving target.

Also, from my catalog 35, Vp is given as:

LDF3-50 88%
LDF4-50 88%
LDF5-50 89%
LDF6-50 89%
LDF7-50 88%

So even that varies in a random fashion.

Regards,

Wes

absolutely correct Hal, the chinese do not consider references to themselves and tea to be racist

but, the gay population in the USA does, and they are the ones calling all the shots these days

the latest controversy has started when one guy in another thread came up with a word problem about two gay tea bags getting married on a chinese persons table in china, that one is not expected to blow over soon, just best to be cautious and not mention any organic matter in the same reference with a particular race or geographic population

It is not clear that Radio Shack sells the pushup masts anymore.
I got the last one at our store.

Rohn made them and they went bankrupt.

You might use Google to search the web for pushup antenna masts.

I used to use a wooden mast to support my folded dipole. it was based on a
mast in
the ARRL Handbook or Antenna book. It consisted of an 8 foot treated 2 by 4
planted in the ground. This was "double carriage bolted" to a pair of 20
foot pair of 2 by 4
which was double carriage bolded to a single 20 foot 2 by 4. At least 3
feet overlap
between sections is desired. I did not find it necessary to have a guy. I
attached the center of
the folded dipole to a hook at the top of the now 35 foot mast.

The only problem I see is the cross section of the 2 by 4 in 125 mile per
hour winds. If the lower
20 feet were up against the house, you might not have a problem. Otherwise
guys will be essential.
Probably 3 at the top of the pair of 2 by 4s and two (one to either flat
side) of the top piece.
Make certain that you get strong lumber, preferably not pine.

Regards,
Ed, N5EI

Yes, and Andrew sometimes changes their philosophy about specs to meet certain marketing realities. I was involved in a competitive situation where my proposal for an offshore broadcast RF system included some Andrew HeliaxT. The tender spec called for a certain power rating for the coax, which by its published catalog, Andrew did not meet for the line size they proposed to us as compliant. A similar line size by an EU Andrew competitor had been bid to the end user by another tenderer, which by their spec was compliant to the tender. The customer asked for clarificatication from us/Andrew. The difference was due to Andrew's inclusion in the spec of a solar derating value for their cable, where the competitor's did not. Andrew proved their point (through us), and my proposal won.

Not long after that, Andrew changed all the power ratings for their cable, removing the solar derating factor, and advising users to apply their own based on derating information they added to the catalog (similar to derating for SWR).

Also note that cable attenuation and power ratings are dependent on, and stated by most OEMs only for specific ambient temperatures and a specific load SWR (1:1 in the case of Andrew).

Yes, Radio Shack used to carry them, but not any more, unless you just happen to find one in a store left over from when they had them. Someone said Lowes had them, but the stores in the S.F. Bay Area don't - - and in an on-line search of their stock they don't recognize the product, so maybe that's dated information, too. I suspect with cable and satellite, hardly anybody goes to the trouble of putting up an outside TV antenna any more, so from disuse, we may have lost that resource. There still might be masts available through small town TV installers in the fringe area around big cities, but I don't see anything on line except for Wholesale Electronics Inc who have no stock on hand. The latest manufacturer to take over some of the business from Rohn, Nello Corp. says they will have a line of telescoping masts in the Fall of 2005, so you might be able to get one then through Array Solutions on the West coast or AN Wireless in the East..

If anyone reading this has a 30 ft 3-section TV mast they're willing to sell for a reasonable price, I'd be interested myself.

73, Chuck W6PKP

2280. reflectivity of wire mesh (wire screen)

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-02 19:52:29 UTC
From: Wimpie <wimtel@tetech.nl>
Message-ID: <1120333949.135501.228840@z14g2000cwz.googlegroups.com>
Source record: 73895

Hello,

Wire mesh or parallel bars are often used as a replacement for solid reflectors.

Is there any practical formula, computer program or graph for calculating the (plane wave) reflectivity/reflection coefficient of wire mesh (for example chicken mesh)?

I am thinking of a formula where you have to enter cell/grid size, wire thickness and frequency.

With kind regards,

Wim Telkamp

I may have generalized too much. Since I found old mag-mount cb antennas at flea markets and hamfests I assumed anyone could do the same. They were not sold as "magnets" - they were sold as old mag-mount cb antennas. The magnets just happened to be at the bottom of the antennas.
I suppose different flea markets have different offerings at different times.
I should not generalize. I should have given you a story of how I had found magnets, and infer that similar actions may have similar results.
My apologies.

be careful attaching it to the house. The amount of overhang will affect
that task.
Take a look at the power company's service entrances to most homes. Most
will penetrate the roof and come down a wall. Some use "unistrut" and
"unistrut straps" to mount pipe to a wall - available at an Electrical
Supply house like Graybar. If you use 2" heavywall galvanized conduit - and
fill it with concrete, it will resist bending pretty good. Mount a pulley on
the top to raise the antenna.
If you try to attach the pipe to just a facia board, remember that the
facia board *could* come loose.

Hmm, Radio Shack used to carry telescoping masts; no more though,
according to their web site. However, Lowe's Home Improvement does
list a guyed 30-foot telescoping mast. Probably special order.

Oh, well...

See if a farm supply house or welding shop has some of those square steel tubing...they usually come in 22 ft lengths. You can then get one that will telescope in a slightly larger one.
A pier pad at the bottom should be enough to support the bottom and they are very stout, but still can be raised by one person, and you might find that kind of mast won't require guying.

If you can find a competent machinist in your area then purchase two
decent size pipes and have the machinist install a base seal so you can
force mains pressure into the base , the centre pipe will lift and then
can be locked at full height or dropped in moments.. hope you follow
what I mean .Ten metres is very achievable for little outlay , a simple
short guy and bracket to the house will strong if installed correctly ,
talk to a carpenter for good advice .Good luck.

If the cell dimension of the grid is 1/20 wl the grid is considered to be effective as a continuous reflective plane. The same dimension of spacing between parallel wires is also effective as a continuous reflector for EM waves whose polarization is parallel with the wires.

Ok, as I stated earlier, I am working from published specs rather than
my own measurements, and I understand there are issues about the
reliability of published specs.

I didn't plot the values on graph paper to find A and B (or k1 and
k2), but used a least squares regression to find A and B (and r**2,
the correlation coefficient as an indicator of the quality of the
fit).

What I was trying to do was to develop an RLGC model for the line from
published figures (attenuation at spot frequencies, nominal Ro, vf),
and I can do that. The issue about the dielectric came up in trying to
reconcile the G / D / k2 figures with the knowledge that the cable had
PE dielectric and should have had D=2e-4 (I stand corrected on my
misreading of the value 2e-5 from my ITT Handbook by Wes - thanks).

The purpose of the model and validation are for my online transmission
line loss calculator.

The notes to the calculator show the modelled loss vs the data points
in one of the graphs at http://www.vk1od.net/tl/tllc.php .

>D can vary noticeably from one length of cable to another manufactured
>from a different batch of nominally identical materials.
>

Ok, noted. I have added a few words to the explanatory notes on the
calculator.

Thanks for the help all.

Owen

http://albums.photo.epson.com/j/AlbumIndex?u=4030688&a=31812523&f= is
everything that I have in my base station setup in a junk room. Will
be adding a rotator when I get my Maco Y Quad antenna set up. Maybe
I'll be able to get out and do some talking then.

I don't know what I am going to do with my antenna setup on my pickup.
I am running, now, as I originally started out with, a single Tram
Penetrator (Monkey Made - ran it a while co-phased but couldn't really
tell the difference in tx/rx AND robbed it cause I needed one more of
the Tram's to make up the horizontal dipole!) I have it mounted on the
side of my metal toolbox and it does a fantastic job. Only thing
is?!?! I am thinking of putting a 'tonneau?" cover?, youo know the hard
plastic shell that covers the complete bed. Where in the same hill
will I be able to put the Penetrator at?

Any and all suggestions will be greatly appreciated!
Take care God Bless
Cliff

I believe that when the openings in the grid are half of the
wavelength, half the signal (-3 dB) gets through and half is
reflected. As the gaps get smaller, more signal is reflected. I've
never seen a formula for it.

Owen,

Are you aware of programs -

RJELINE2, RJELINE3, for balanced pair lines,

and COAXPAIR, COAXRATE for coaxial lines ?

These are based on exact, classical transmission line formulae and
will tell you all you could wish to know about behaviour of
transmission lines versus any complex termination from open circuit to
short circuit. No approximation of critical parameters.

However, in the coaxial case, dielectric loss is an input quantity.

Yes, of course, Reg, they and the rest of the suite are interesting...

In validating my calcualator, I have compared it to yours, Dan's
XLZIZL / TLD, Dean's TLA and Kevin's java applet. They all produce
slightly different results, one of the reasons I have tried to
document the assumptions that underly my calculator.

Yes, I played with a model of Belden 8262, it is pasted below, and
will probably be line wrapped by a lot of news readers.

I have plugged in the dimensions from the 8262 spec sheet, and it
produces some results that are inconsistent with the specs. The
insulant diameter from the spec sheet is 4.5mm, loss/Km 13dB. (The
value for O was chosen to calibrate the DC loop resistance.) At 1GHZ,
the calculated loss was 35dB against spec of 21dB.

I played with it for a while trying to calibrate against the B8262
specs, but was unsuccessful.

2303. Re: Modeling TL "dielectric" loss

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-03 08:33:42 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <11cf8n9cu87h933@corp.supernews.com>
Source record: 73919

If you want to work from published specs, you should find this interesting, from the Belden catalog:

It looks like 8214 and 9913F7 are the same except that 9913F7 has a solid aluminum shield between the insulation and the braided copper shield. 9913F7 claims lower loss, amounting to 0.9 dB at 400 MHz. One might conclude that the difference is due to the extra shield, presumably because it's smooth and not braided.

It looks like 9914 is the same as 9913F7 except that 9914 has a solid rather than stranded center conductor. The spec for 9914 shows less loss, amounting to 0.4 dB less at 400 MHz. One might conclude that the difference is due to stranded vs. solid center conductor.

I think your analysis isn't valid for two reasons. The first is that you're relying on published specifications. (For example, I just measured the Z0 of ten "50 ohm" cables of different brands and types I have on hand -- it ranged from 44.6 to 56.8 ohms. I already reported a loss measurement that was quite different from the spec.) The second is that your model is overly simplified. It looks like you're trying to account for all the loss mechanisms in a coax cable by considering only the dielectric and conductor losses in idealized materials, or at best two factors which are proportional to F and proportional to the square root of F. In order to get a decent fit, I think you'll have to include additional factors for such things as the effect of stranding the center conductor and the extra loss associated with a braided shield, which might well be different functions of frequency. Of course, tinned conductors, which are very common, will alter the loss characteristics depending on the composition of the plating, and change the shape of the loss vs. frequency curve at a frequency depending on the depth of the plating. Once you start really digging, I think you'll find other mechanisms, such as perhaps how tight a woven shield is -- it wouldn't take much of an air gap between the shield and the insulation to have some pretty noticeable effects.

I went through this excercise of attempting to predict coax cable loss many years ago (my notes say 1991) and abandoned the effort as being too time consuming. I hope you'll be willing to devote the time and effort necessary to come up with a reasonably accurate model.

Roy Lewallen, W7EL

==========

The greatest source of divergence between manufacturers'
specifications and what you think you've actually got is due to
manufacturing variation in cable dimensions.

Such as :

Inner coaxial wire diameter as it is drawn through diamond dies.
Ovality of wire drawn through worn dies.
Tightness of stranded inner conductors affecting diameter.
Diameter over the extruded polyethylene insulant. Affected by
temperature.
Off-centre eccentricity of inner conductor within the insulant.
Ovality of the polyethylene extrusion.
Diameter of braiding wires.
Tightness of braid over polyethylene.
Longitudinal tension in braid.
Tightness of copper or aluminium tapes over polyethylene.
Tightness of PVC jacket or other protection over braid or tapes.

- and a dozen other dimensional factors which I have long forgotten.

There's also variation in the conductivity of annealed copper wire and
contaminants in polyethylene due to lack of cleanliness in storage.

During manufacture, as the product is drawn through machinery,
electrical characteristics change. They can become cyclic. When
measuring long lengths small reflections can accumulate causing
attenuation versus frequency curves to exhibit a slow ripple about the
average slope of A*Sqrt(F)+B*F dB.

(The most unreliable manufacturer's specification I have seen,
associated with attenuation and power rating, allowed cable to be used
at a temperature of the melting point of polyethylene. Would burn the
skin off your hands. Testing equipment????)

Important factors are the inevitable errors in all measuring
instruments, especially so-called SWR meters, and the delusions of
accuracy usually suffered by everybody involved. It's so easy to draw
the wrong conclusions!

That would work. The problem that it is pricy (Yaesu-$320), heavy (8 pounds), may not be enough to handle an HF tribander.

I had an Alliance Tenna Rotor for years. It worked well and only cost
$50 used.

The only other alternative might be to create yourself a bracket that
you can loosen. Lower the antenna part way, Loosen the bracket and
turn the antenna by hand. Then finish lowering the tower.

The only other alternative I see that you haven't rejected is to mount
the beam vertical and leave it that way when you raise the tower.

Good luck

2310. Evaluating location for radio activities

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-03 14:55:29 UTC
From: Dennis Gibbs <R390A@cox.net>
Message-ID: <I%Sxe.52790$R21.3417@lakeread06>

Hello all,

I am beginning the process of searching for some land on which to build a home. It will be located in the Pacific Northwest, in a fairly rural area. I expect to indulge myself heavily in my radio hobbies, including ham radio (especially on the HF bands) as well as a fair amount of Short Wave Listening. I would like to solicit advice on how to evaluate a potential location for quality of radio reception.

Aside from the obvious (i.e., a high elevation, away from high voltage power lines, plenty of room for antennas, etc.), are there any other attributes I should consider to ensure the location will be conducive to my radio activities?

Dennis

>Pref2, Vref2, Iref2, including magnitudes and phase angles
>for all voltages and currents. Source is unknown. Load is
>unknown. Lengths of feedlines are unknown.

Without disclosing the answers or the exact procedure for solving the
"brain teaser", I would like to draw attention to some of the implicit
relationships that "ought" to help.
1) It is assumed that both feelines have purely resistive
characteristic impedances (imaginary component, Xo, is zero).
2) Regardless of the length of the 300 ohm line and its termination
impedance, the standing wave pattern and the voltages and currents,
both incident and reflected as a function of distance x along that
line are determined completely by the requirement/condition that there
is a Z0 match at point "+".
3) There are an infinite number of lengths of the 300 ohm line and a
corresponding infinite number of termination impedances for that line
that will produce a Z0 match at point "+". However, because of (2),
above, some of those combinations are well known combinations with
well understood results (e.g., odd multiple of quarter wavelength or
an integer number of half wavelengths).
4) Due to conditions (1) and (2) above, the phase relations between
all of the voltages and currents immediately adjacent to either side
of point "+" are trivial (i.e., any two quantities chosen will be
either exactly in phase or exactly 180 degrees out of phase with one
another).

Due to (3) and (4) above, it would seem that an arbitrary choice of
either a quarter wave line with an 1800 ohm termination or a half wave
line with a 50 ohm termination would provide a convenient example with
which to begin an analysis. However, that is not necessary and only
provides a crutch to get off dead center.

If all of the above elements are kept in mind, then it becomes a
matter of solving a simple algebraic relationship involving 4

equations with 4 unknowns (the incident and reflected voltages and currents at the right hand side of point "+").

The actual numerical answer to such a problem is irrelevant. The points to be learned from all this are really the implicit relationships (2), (3) and (4) above. Without an understanding of those points, it is virtually impossible to even know where to start. I think that is the real point that Cecil is trying to make.

Why just ''high voltage'' power lines? I'd avoid all power lines.

Yes, the single most important location for outstanding DX on LF, MW and HF
is to site yourself right on the beach.
Much discussion has taken place about the "ideal" DX site and there is
considerable consensus among serious DXer's that DXing on the waters edge at
the beachside gives a major boost to signals.

Good luck in finding the Holy Grail of DX sites

Hi.

I solved the problem by making an impedance packet like the two for 18
MHz and 24 MHz, tuned to 50 MHz and placed between the two existing
coils.
In this way I can move the unwanted resonance up to 50 MHz, where the
normal tuning of the antenna takes over.
I have now a fine SWR on 50 MHz.

2316. Feed Line Length - Ladder Line

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-03 17:50:55 UTC
From: Pat Whelton <pwhelton@earthlinkNOSPAM.net>
Message-ID: <3AVxe.429$BK1.219@newsread3.news.pas.earthlink.net>
Source record: 73782

I've had a store bought (so sue me) dipole fed with 600 ohm ladder line up 35 feet for about a year and a half now and I love this antenna. It's 66 feet in length and I can pretty much tune everything from 40 through 10 meters with a Dentron Super Tuner. This thing came with 50 feet of ladder line and I have it draped all over the place trying to take up the slack before it finally feeds into the shack.

My question is can I safely cut some of this excess ladder line off? I assume that it will impact the tuning but I'm also assuming the tuner will take care of it. I guess I can always cut it off and if it doesn't work I can wire nut it back together again. It just looks sloppy with all this extra feed line drooping off the roof and suspended by the fence (and over to grandma's house we go) before it finally comes into the shack.

Your thoughts are appreciated.

I was at Quintana beach, at the mouth of the river.
Basically Freeport TX. I was parked on the beach, right
where the beach makes the turn north at the river, on the
east side of the river. Anywhere on the gulf coast is a good
place to play radio. It's all rated the top "30" rating as far as
ground conductivity. If you are nearly on the water like I was,
you can really brown the food with a good vertical. I had to
keep moving the truck up, as the tide kept coming up. Almost
got stuck once... :(BTW...The fishing that night was lousy...
I did much better at the BBQ and the radioing..MK

Actually, it is one mm broader than that. In the above analysis, an energy analysis works just as well as any other, contrary to the Sacred Cow Lamentations I and II of some experts on this newsgroup. There is so much redundancy built into the voltage, current, and power relationships in a transmission line that there are a number of valid ways to skin the cat. An energy analysis is one of those valid ways. Two people have sent me emails with correct solutions. Here's how to approach the solution from an energy standpoint.

---50 ohm feedline---+---300 ohm feedline---
Pfwd1=100w--> Pfwd2 not given-->
<--Pref1=0w <--Pref2 not given

rho=250/350=0.7143, rho^2 = 0.51, (1-rho^2) = 0.49
rho^2 is the power reflection coefficient.
(1-rho^2) is the power transmission coefficient.

Pfwd1*rho^2 = 100*0.51 = 51w reflected back toward the source at the match point. My article labels that quantity 'P3'

Pfwd1*(1-rho^2) = 100*0.49 = 49 watts transmitted through the match point toward the load. My article labels that quantity 'P1' (as does Dr. Best's QEX article).

For a match to exist Pref2(1-rho^2) must equal 51w, the part of Pref2 transmitted back through the match point, i.e. not re-reflected. My article labels that quantity 'P4'

That makes Pref2 = 51w/0.49 = 104.1w, and makes Pref2(rho^2) = 53.1w, the part initially re-reflected. My article labels that quantity 'P2' as does Dr. Best's QEX article.

So Pfwd2 = P1 + P2 + P3 + P4 = 49w + 53.1w + 51w + 51w = 204.1w

Who said powers can never be added? Pfwd2 is indeed 204.1w.

Now that we know all the powers (without knowing a single voltage) we can calculate the voltages and currents whose phase angles are all either zero degrees or 180 degrees. As Bob sez, phase

angles are trivial at a Z0-match point.

Is there anybody out there who still believes that an energy
analysis is impossible and/or "gobbledegook"?

Incidentally, the two 51w component powers represent the amount
of destructive interference energy involved in wave cancellation
and the amount of constructive interference energy re-reflected
toward the load as a result of that wave cancellation. This is
something that Dr. Best completely missed in his QEX article.
He correctly identified P1 and P2 but completely ignored P3 and P4.
Thus he came up with the equation: Ptot = 75w + 8.33w = 133.33w.
Remember that argument on this newsgroup from spring of 2001?

May be a rash assumption. Trimming the feedline will change the
impedance the tuner sees and the tuner may (or may not) like the
new impedances. How about downloading the free demo version of
EZNEC from www.eznec.com and seeing for yourself what the
tuner will see?

>

You need to drop by the local building codes office. Your home site will be located in a county or inside a city or town limit. Rules vary from place to place but every place has building codes and inspectors who inspect construction to ensure the codes are enforced.

Code enforcement varies from place to place -- I built houses in West Virginia, southwest Virginia, northeast Tennessee, and southeast Kentucky -- there were some counties where we never saw an inspector and the guy who issued our building permit at the county courthouse could not even read blueprint house plans -- but in other counties they inspected us at every turn.

If you are building in the county -- outside city or town limits -- the county will inspect you. If you are building inside a city or town limit, their inspectors will inspect your construction or they may use the county inspectors, or, your construction may be inspected by both county and town/city.

You need to check with the inspector's office or whichever office issues building permits to see if they enforce codes on towers and antennas. You may find that you can put up any tower, any height, anywhere you want -- or -- you may find that putting up even the simplest antenna support will require engineering drawings, environmental impact statement, and several inspections. Remember, too, if you are in the flight path of an airport, even a local grass strip, you will have height limits and lighting requirements on towers.

Also, you are likely to be wiring your house for a ham station, which means one room or one corner of the house will have several 110VAC outlets plus one or more 220VAC outlets for linear(s). The electrical inspector will find this strange and you need to talk with him BEFORE you even think about building so you get him on board with you -- he will tell you what the codes require so you don't have to rip out any wiring. Don't forget, too, that you will need some way for cables to go out of the house to the antennas -- and anytime you poke a hole in a wall, the inspectors get nosy -- you will need to ensure that the cable egress location has proper sealing, fire blocking, insulation, etc. Also, you'll need to ground the station -- talk to the inspector about that because he may look askance at a #4 copper wire running to a ground rod in addition to the one required at the entrance panel. Remember, too, when you start laying out your floor plan -- if you have water (a sink) within a few feet of the ham station, the outlets may be required to be GFCI protected -- and you don't want GFCI on your ham station outlets because you will forever be tripping the GFCI and shutting off the power -- so locate the ham station away from sinks and faucets.

Bottom line: Find your local building codes office and get to know them LONG before you select a building site.

50 foot is a neat length in that if you plot all the impedances at the
various bands you fill find a current max fairly close to 50 feet.

Cutting the length may move you closer to a match on some frequencies and
further away, and beyond the range of your tuner on others. I am not
familiar with the specs of your tuner so can not be more definitive.

All this being said, cut it, if your tuner matches it your golden. If not
reattach the cut section.

Take a look at Cecil's site, he has an antenna that he tunes via feedline
length. He has a number of graphs and a smith chart that will answer your
questions.

Hi Dennis:

I would look into local Zoning laws to make sure someone won't build a Power line / Station / (etc) next to your home.

Hire an architect . Tell Him /her about what you want in the way of RF free wiring; Heck, approach an architect / EE instuctor at a local college & see if designing your RF free house electrical set up is a possible project for a student....

Do site surveys, with some wide range receiver, looking for noise where there should be none (Consult radio Astronomers for this ??)

Use a log book for problems / Pluses, then compare locations using a spread sheet.

If your house is in a rural area, RF Free, it's going to (Probably) be good for Astronomy as well.. Walking around the Moon with a telescope is always fun.

In closing, sounds like you have the world on a string; Congratulations !!

Dan / NYC

Hi Cecil,

I know you like to tout ladder-line/tuned feeder as the solution for
everything from SHF to ingrown toenails... but don't you think you're
a bit over the top this time? Kevin should be able to get full-band
SWR under 1.5 using convenient coax feed, with no worries about
fussy window line, and no tuner of ANY kind, including tuned-feeder.
And you suggest he deliberately create a 5:1 or so SWR at the antenna
by using a mismatched feedline, just so he can have the joy of building
and using a tuned feeder??? Sheesh! Horses for courses, Cecil.

Pat, the correct length for a feedline is that which reaches from the feed point of the antenna to the terminals of the tuner.

Having used the Dentron Supertuner I doubt if you'll have any trouble matching any impedance you'll find at the input of the feed line.

If it doesn't match on any particular band there are four ways to achieve the match, depending on the specific impedance at the input of the line. Try a series cap in the line, or try a parallel cap across the line, or do the same thing with an inductor to see which works. It's cut and try, but it's better than having the line coiled up in the bathtub.

Walt, W2DU

Cecil already defined the voltage and current at
the match point when he gave the characteristic
impedances of the two lines and the rate of
energy transfer through them. Knowing the voltage
and current, anyone can calculate
Pfwd2 and Prev2 using Pfwd2 = |(V+IZ0)/2sqrt(Z0)|^2 and
Prev = |(V-IZ0)/2sqrt(Z0)|^2, where Z0 is the characteristic
impedance of the second transmission line.
Cecil's ability to add powers together, which he did in
this instance, isn't anything unique, and doesn't
really teach anything about the general case.
In fact, for a quarter wave transformer, you can
do the following trick: compute the value of the
power as it just comes through the impedance discontinuity
for the first time and call it Pa. Call Rho^2 at the
load P. Then the power delivered to the load will be
Pa(1 + P + P^2 + P^3 + P^4 ....) which looks the
same as if the power reflection coefficient looking
back toward the generator was 1 and the power at the
load was the result of the addition of an infinite
number of reflections. Such an interpretation, though,
can be shown to be absolutely wrong. Can anyone see why?

Thanks Roy and Reg,

I understand your point that the calculation engine is more precise
than the model accuracy (against specs), and the product manufacturing
tolerances introduce an even larger error in the predictions. Not
mentioned, but installation and through life degradation introduces
yet another uncertain and possibly greater issue.

Appreciate all the input.

I am sure you are right Roy, this could go on indefinitely. I think I
have gone far enough for the purpose, probably too far, but that is
the cost of confidence that I have gone far enough!

Thanks again.

Owen

I'm not familiar with the TS-830 so I assumed he had a real problem.
It's a sub-set of the same problem I solved with my 20m rotatable
dipole. I provided the same solution I presently use and with it he
gets the added bonus of 20m-10m operation. BTW, 13 cent/ft 450 ohm
ladder-line with a 9:1 SWR is a lot less lossy than 13 cent/ft coax
with an SWR of 1:1. He gets all band operation above 14 MHz and greater
efficiency for half the price. Why is that over the top? :-)

I'm glad you agree, Tom. Other experts on this newsgroup
will argue with you as they have with me for four years
ever since Dr. Best posted his infamous Z0-match equation:

Ptot = 75w + 8.33w = 133.33w

to which I objected back then, only to have most of
the rest of the posters agree with Dr. Best. I was
dumbfounded to see so many otherwise knowledgable
engineers agree to a violation of the principle of
conservation of energy. I was told not to worry about
conservation of energy - that it takes care of itself.

Destructive interference between the external reflection
at the match point and the internal reflection from the
load supplies additional constructive interference
energy to the forward wave in the quarter wave transformer.
You didn't include that constructive interference energy
above. Hint: That virtual power reflection coefficient looking
rearward into the match point doesn't reach 1 until steady-
state is reached (wrong premise above). The virtual power
reflection coefficient looking forward into the match point
also doesn't reach 0 until steady-state is reached. Those
two virtual power reflection coefficients actually start out
the same value and proceed in opposite directions during
the transient buildup to steady-state.

Hi Cecil,
you come up with the right answer, but is your interpretation correct? Can you do the same thing in a general sense? If there is no Z0 match between the two transmission lines, does your method still work? The little conundrum I posed is an example of a procedure that will actually give the right answer, but the interpretation I gave of how it works is wrong. Can you be sure your method doesn't have the same flaw?
73,
Tom Donaly, KA6RUH
(P.S. The method of using V and I and the junction of the two xmission lines to find the forward and reverse powers on a transmission line doesn't prove the powers exist. It works just as easily with a pair of resistors and is more an algebraic stunt that works than anything else. It does agree with you, however.)

Hi again, Cecil...

I think the "problem" here is that you tend to superimpose your
priorities over those of the original questioner:

"I know that I can only use it close to the cut frequency, but want
to build a small tuner to allow me to go off the cut slightly.
I only want the tuner to be used on 20m..."

Multiband operation, while desirable in my book, was not
something Kevin asked for. He also did not say he wanted
the cheapest possible feedline.

As to loss, if Kevin needs as much as 100 feet of feedline, and
wants to use a conveniently small cable like RG-8X, he can
expect to lose 1.5 dB or so. That might be a dB or so worse
than window line--if the latter is in a favorable environment.
Kevin would need mighty sharp ears to tell the difference.

73, Ed

> transmission lines, does your method still work?

As a stand alone analysis, it yields two possible solutions
but the purpose of this discussion is not to come up with
a new stand alone method of analysis. The purpose is, given
a standard analysis, to add TRACKING OF THE ENERGY COMPONENTS
through an impedance discontinuity, something many people
believe to be impossible.

It wasn't designed to work as a stand alone analysis but
it does for Z0-matched systems, the most usual ham
configuration. However, an additional piece of information
is required in the general case to be able to tell which
voltage is leading and which is lagging.

> (P.S. The method of using V and I and the junction of
> the two xmission lines to find the forward and reverse
> powers on a transmission line doesn't prove the powers exist.

Do you think the powers defined in HP App Note 95-1 exist?
Remember my one second long transmission line example where
the number of stored joules exactly equaled the number of joules
required by the forward wave and the reflected wave? If the
energy is not in those waves, where is it? Nobody has
provided any explaination of how standing waves can exist
without forward and reflected waves. Under "standing wave",
The IEEE Dictionary says: "A pure standing wave results
from the interference of two oppositely directed traveling
waves of the same frequency and amplitude." i.e. standing
waves are the result (effect), two oppositely directed
traveling waves are the *cause*. Most of my references
agree. The forward and reflected wave energy components
must exist as causes before standing waves can materialize
as an effect.

Source record: 73804

If I mount the Penetrator there, the very top of it might come even with the top of the cab. I have been told, by them, whomever them is, that the loading coil on any antenna needs to be above cab height Will I need to go to the old standby, the 102" stainless steel, DEFINITELY NOT ONE OF FIBERGLASS! I have seen a couple of advertisements for those. I just don't see how that, made of FG, antenna could ever last very long.

I wonder if taking a piece of conduit, I have an antenna mount that is made of 1" or so of metal, has the curves in it to mount on pipe and such. I would not be using the curved part but taking self-tapping screws screw that mount to 3/4" conduit or so and then mount that conduit to the bed of the truck, in between the cab and bed, before the cover was put on. Would use U-bolts to mount the conduit, a minimum of three of them. And by mounting it there, make the coil stick up XX above the cab of the truck

I am not familiar with a screwdriver antenna setup. Is it for 2-4-6 or even 10 meter?

Hi

I totally agree. I live a couple blocks from the beach, and when I take my portable down to the beach, I pick up tons of SSB frequencies. I mean a bunch. It's like the signals have an unobstructed line completely.

Lucky

Electrical Length in degrees = 360 degrees for each wavelength divided
by the velocity factor.

==========

It depends on frequency, its physical length and on its propagation
velocity.

Velocity Factor (VF) = Actual velocity on line / Velocity of light.

It is sometimes better to refer to length in wavelengths rather than
degrees.

One wavelength = 360 degrees. 1/4-wave line length = 90 degrees.

I'll leave somebody else to write down the actual formula for the
number of degrees in a given length of line in metres, at a given
frequency in MHz and given VF. I'm too tired.

Reg.

2356. Mosely TA-33M info help

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-05 01:28:33 UTC
From: Ken Bessler <kg0wx@NOSPAMyahoo.com>
Message-ID: <8nlye.7396$Eo.5443@fed1read04>
Source record: 73820

I just picked up a TA-33M in great shape for $100. Got 30' of Rohn 25G for another $60. I marked all the components so there will be no cunfusion but I am unclear on one point.

I've got the locations of all elements marked but I need to know if the driven element is closer to the reflector or the director? I've got the boom marked where the elements go but I forgot to put a mark as to which end of the boom is "forward" hence gets the director.

Also, how high (minimum) should this antenna go? I've got a friend who has one at 20' and he thinks I should try for twice that.

Help?

If an agent, a representative of an insurance company, sells and the company accepts a property then anything that happens (if fortuitous, or accidental) to that property is covered as long as it falls within the policy language, perils insured against and property covered.

The company can't come back AFTER a loss and deny payment because of something not defined in the policy. They can't just make it up after the fact.

Take the line outside at night where you can hear crickets chirp.
Count the number of times it chirps in 15 seconds, and add 40.
Thats the degrees. (temperature).
http://www.srh.noaa.gov/elp/wxcalc/formulas/cricketChirp.html
Now measure the transmission line,
Then get a copy of the ARRL Antenna Handbook
or the ARRL Amateur Radio handbook,
and find out why you asked the wrong question.

I'll bet that there's "language in the policy" that is sufficiently vague and flexible such that the company can stretch a loophole for anything that it wants. Maybe I'm too paranoid, but the insurance company expects that an insured property is a normal and typical example of materials and construction, and that due care was applied to the design. Further, the property should be in compliance with local existing building codes and standards.

If you wired half your house with lamp cord, never got a permit, and have no record of inspection, do you think the company agent should know this by himself? If the loss is big enough, and especially if there's some unusual circumstances (fire inspector's report, neighbor's claims), then the company's lawyers have plenty of room to work in. You may have the utmost confidence in your own workmanship, but, if the insurance company is trying to avoid a $500k claim, all they have to do is say "no." So then what happens? You take the insurance company to court, and they ask you about your experience in soils engineering, concrete construction, structural engineering, calculation of wind loading, welding certifications, experience with lightning protection, etc. They will cut you up into very small pieces.

Everything unusual about your property should be defined, and if your agent is still eager to sell you a policy despite your "creative engineering", then I would start to wonder why the agent is so desperate to sell policies.

2363. Re: Antenna Tuner for 20m Dipole - Build

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-05 07:07:51 UTC
From: Kevin & Natalia <sparc_man@hotmail.com>
Message-ID: <42ca3e0c$1@news.iconz.co.nz>
Source record: 73729

Hi All,

Thanks for all the information, there was plenty to think about, and decide to do.

Just for the record, I wanted a simple dipole, using coax, as it is easier to work with in my home, no windows near to run ladder-line.
I do agree that ladder-line would of made it work better across other bands with a tuner, but I just wanted something on 20m.
The rig, TS-830S, being tube finals, from the information will allow me to tune off the cut frequency with tuning the tubes. So I will be able to move across the band without too much problem.

I have the dipole cut and ready to go up, was going to do it today, however the rain came down, and washed that idea away, have to wait for the weekend now.

Again thanks to all.

Kevin, ZL1KFM.

2364. Re: A Single-Core 4:1 Current Balun

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-05 07:23:06 UTC
From: W8JI <w8ji@contesting.com>
Message-ID: <1120548186.277018.174050@g44g2000cwa.googlegroups.com>
Source record: 73730

I think the basis of Chris' claims is that equal and opposite currents flowing in two parallel or concentric conductors makes it a "transmission line". I can give examples where that isn't true. In any conventional transformer with a load across the secondary, the secondary current will flow opposite the primary current based on Lenz's law. It is magnetic field coupling from aprimary to a secondary that causes that effect.

KD5WNA probably just didn't read the application note carefully, and missed that part 1 covers transmission line transformers and part 2 just transformers.

Every peer reviewed textbook I have that deals with transmission lines states they transfer energy via TEM mode (transverse electromagnetic mode, not electric magnetic as the "tutorial" by Trask states).

The key is all in the excitation and termination of the windings.

There is a great deal of difference in how energy gets from one place to the other in the two systems. That's why bandwidth is restricted in a conventional transformer mode, and loss over wide bandwidths is generally higher in a transformer rather than a transmission line mode of coupling.

The real title of Chris' tutorial should be "What I Think a Transmission Line Is", because that's all he really disagrees with me about. I think a transmission line conveys energy via TEM mode, he thinks it conveys energy through flux coupling. We simply have a disagreement of definitions. I was speaking very specifically about a balun Sevik described that would not provide a balanced current source. Chris has extracted certain sentences from a long exchange to prove some unimportant point about him being right and me being wrong, and totally skirted the issue of Sevik's design being flawed.

The tragedy of this is some people will think Sevik's design is a good one, because if Chris is right about this one thing I must be wrong about everything I said regarding Sevik's not-too-good balun suggestion.

Um ... let me guess ... you don't carry a general liability rider?
Or if you do, you were not careful to read the details?

They are not expensive, and will cover anything ... and can even
cover intentional neglegence by the owner. Every ham with a tower
(or a pool, or horses, or a big dog, or ...) should have one.

Yes but you need everything first insurance with one company and then at
the maximum but the minimums. You pay dearly for a general liability
rider if you take it all into account. Yes you are protected.

You might want to go to their web site, and figure it out from the picture.
Look at the location of the mounting plate.
>
> Also, how high (minimum) should this antenna go? I've
> got a friend who has one at 20' and he thinks I should try

That depends on whom you talk to. One rule of thumb is for the height to be
one wavelength. I have a TH3 at 40 feet, which would put it near optimum for
15 meters. I used to have a TA33JR at 28 feet, still had a lot of fun and
made lots of contacts on all three bands.

> Any constructive help gratefully welcomed

Hey, I take it you guys don't have military surplus outlets? Surely !!
What about pump up field masts and the like.....

Otherwise square steel tube reducing in diameter size until you achieve the required total height. Using a piece of heavy steel plate, 900mmx900mm, obtain a 150mm length of box section just wider than your bottom box section piece and weld that section to the plate [your bottom section sits in this] Drill a hole straight through this to accommodate a bolt through both box sections [stops the section being lifted out] Weld a plate that will accommodate a galvanized hand winch [the type used on boat trailers] to the largest bottom section, weld an eye to the top smallest box section [the winching cable attaches to this] Leaving at least 600mm in each extended section, fabricate a collar that will lock each section in place as it is risen upwards [to stop it falling] Or weld two nuts on each top section side, drilling the centres away for a bolt/set screw to fix through, which will then stop the box sections from sliding back down. Choose a cable of suffcient winching breaking strain. Crank away until the desired height is obtained, locking each section in place. Reverse the procedure for dropping down. Attach any guy wires to additional eyes on various sections, which should be welded on at each section top. Choose a secure and fixed location for the floor plate. If you don't utilise or need a floor plate, fabricate fixings that will be able for the bottom section to be fixed to the wall [stand off's] Sounds a big job but it's easy done and not megga bucks either. Not knowing what a 125MPH hurricane is like in the UK, do's it make yer jowls chatter in the wind? LOL
Hey Bobs yer uncle, job done. Cheers Dave

Ummmm..... You have to specify the species of cricket. Each species has a
characteristic chirp factor.
Also are your degrees F, C or K?

Charlie:

Bet when you started out, you would never have thought so many petty hams existed.

All you need to do is beef up that setup a bit and smile at all the losers here. Jealous "old women hams" of a envious and vindictive nature.

Just laugh a bit when they sit out there eating the signal off the 90 foot beast.

Perhaps you can, once in a awhile, be kind and offer to, "Let them sit on it!" <grin>

Yodar, where are you shopping? Go to Lowes or Home Depot and get #14
stranded wire, plexiglas for insulators, and screws, nuts and bolts to
put it together. Get some 450 ohm ladder line (Wireman, w7fg I think),
or make your own from wire and PVC from Lowes. To put the whole thing
together should be 30 minutes or less, I do it every year at field day.
Make the dipole as long and high (within reason) as you have room for,
and the 450 ohm line long enough to get from the antenna feedpoint to
your tuner. There you have what you have been shopping for.
Radioworks among other folks have pre-put together antennas, but
where is the fun in that?

You would be hard pressed to beat the VanGorden antenna. 130 foot stranded wire dipole with 100 feet of 450 Ohm ladder line. All insulators, ready to go for $29.95 delivered to your door.

Hi John and thanks for those remarks....

Well no I did not expect so many "petty hams" but it is just human nature
and the heart of man I suppose to be that way for some folks. Tropical
storm Cindy is coming our way now and I'll see how the tower holds up.

I can sure tell everyone and anyone that the difference from 30 ft to
90-95ft is really astonishing. I doubt this smile will leave my face for
some time. 73 / DX

he probably has one of the 600-ohm fed dipoles from www.w7fg.com

try their web site.

there are also lots of dipole kits at www.thewireman.com

or get the arrl's antenna book & do-it-yrself. fun.

There's a nice A-frame wood mast in the ARRL Handbook that's about 40
feet high, and can be made from just a few pieces of lumber.

Hi Group,

Let's say I have a 15 meter dipole. If I were to take a ferrite core and place a core along the dipole for the lenght of 6 meters, having two cores on either side.

The question is would this antenna now work as a dipole on 6 meters but not on 15 unless the reactance of the core was low at 21 MHz?

Does the core act as a RF block but not as a inductance with a reactance at 15meters?

If it is a inductive reactance, then reducting the lenght of the dipole would bring down swr on 15m.

I have seen the ferrite emi cores which clamp around the wire, would these work for 100 watts?

If I had a way to move the cores along the dipole, I could create a multiband antenna, true?

I am sure there are better ways to do such, aka trap dipole but I like to give this some thought.

> characteristic chirp factor.
> Also are your degrees F, C or K?
>

This is from
http://www.noblenet.org/reference/crickets.htm

The formula for this is to count the number of chirps in 15 seconds and add 39 to calculate the temperature (degrees Farenheit.) If there are 30 chirps in 15 seconds, the temperature should be about 69 degrees F. This formula is said to be accurate within one degree. A variation is to count the chirps in 13 seconds, and add 40.
Sources:
"Cricket thermometers," Field & Stream, July 1993, Vol. 98 Issue 3, p21.

and from http://www.almanac.com/outdoors/crickets.php

we have this:

To convert cricket chirps to degrees Fahrenheit, count number of chirps in
14 seconds then add 40 to get temperature.
Example: 30 chirps + 40 = 70° F

To convert cricket chirps to degrees Celsius, count number of chirps in 25
seconds, divide by 3, then add 4 to get temperature.
Example: 48 chirps /(divided by) 3 + 4 = 20° C

==========

there's apparently a small descrepancy (1 degree) in the sources.

Source record: 73748

The short answer is no. One of the best readily-available ferrites for VHF use is Fair-Rite type 61. At 6 meters, one core of this material will look like a resistor of a few ohms in parallel with an inductor whose reactance is also a few ohms. That combination won't do what you're asking.

Even if you locate a better material, you'll still only have a few ohms of reactance for a single core at that frequency, and the Q is likely to still be not very good. It'll be a long way from making a trap, which is what you're trying to do.

If you want to have a single antenna for 15 meters and 6 meters, you
may find it easiest and more efficient to do what I did with my 20
meter dipole. I cut a 6 meter dipole and hung it under my 20 meter
dipole. I happened to cut the length perfect for 50.125, which is
about where I wanted it. The 20 meter dipole resonance dropped.
however, it was a bit on the high side, a perfect match for 14.336
before hanging the 6 meter dipole. now it is a bit lower, but it is
broad banded enough to cover the entire band at 1.3:1 or less so I
didn't need to trim it.

The two dipoles come together at the coax connector and an 8" piece of
PVC pipe is used as an insulator and hangs from the 20 meter dipole to
the end of the 6 meter dipole to keep the ends away from the 20 meter
dipole.

I have been making and using antennas like this since I was a novice.
The only thing I have ever noticed different from single dipoles is
that the lower bands are more broad-banded on the parallel dipoles.

BTW, the six meter dipole is great. It doesn't compare to my
neighbors with beams, but it is better than nothing, and it is a
dipole.

So Mr SMITH

In your Expert Opinion, and full 100% support of Charlie, let us see your Calculations that this thing is Safe. Im not a tower expert by any means. But working at the Worlds largest Aircraft company as a technical Design Engineer, I know what looks BAD. AND I have helped put many towers up and climbed my share of towers, and I know what is safe and what isnt. I would not go up that one for any money on earth.

Tell me what those trees can hold in upward pulling momentum from those 3 guy lines, and how that thing has not exceeded the capacity for the trees to not eventually SNAP. Tell me how the Power pole, set in the verticle with, will hold those three guy lines perfectly secure, while they are pulling at it in a side and upward movement How with no secure pins are the turnbuckles not going to give way.

The force of the tower alone in the wind and pulling on those trees is enough to make one Queesy just to look at it. Oh and He still hasnt answered what he plans to tell the Power company when they discover his little field mod to thier power pole. Hell its a 200 buck fine if they see you putting a nail in one here.

So please do tell us again Mr Smith.

<snip II>

A dipole cut for the low end of 40M should work "OK" (for
selected definitions of "OK") on both 15M and 6M, as well.

I often work fellas on 6M who apologize for "using a 40M dipole."
Their sigs are usually every bit as strong as others.

Rick:

Do you know the difference between a real amateur and a goof ball
which thinks everyone wants to be an engineer?

Do you know the difference between an individual who can get along
with others and enjoys communicating with them, and them with he--as
opposed to someone which is drain on the groups energy?

Do you know the difference between someone who doesn't wish to impose
his thoughts on someone else and one who does?

Do you know the difference between someone who enjoys life and having
fun and someone just sitting their trying to look half-way intelligent
by telling everyone else what it wrong with everything in the world?

Get a real life. Look around you, it is quite apparent that people,
your neighbors and those around you will have the same opinion of you
which we form here. A leopard cannot change his spots, these social
disabilities you pack through life with you are a burden on those
around you.

Get a therapist and get some help son.

For a 40m dipole running North/South, the major lobes on 6m
would be N27W, N27E, S27W, S27E, i.e. pretty much end fire.
I use my 20m rotatable dipole as an emergency TV antenna
when cable is down.

Hal;

Now don't be picking on my good buddy arnie, he is doing a fine job out there in california for me.

We need him to get those drivers licenses for the illegal aliens. By this time next year I would like to have all the truck drivers which are buying homes, cars and sending their children through college reduced to receiving welfare checks.

It doesn't take a genius to drive a truck and that is one of the last areas a working fellow can still earn a half decent living, time for those illegals to start driving those big rigs for a minimum wage.

With those illegals living 10 family's to a home they can get by on a lot less.

Get with the plan man. We used to export our standard of living to the rest of the world pulling them out from under poverty, disease and death, but that got darn tiring (and our profits from ripping them off under that system were too low.) We replaced that tired old plan with the new one, 'import 3'rd world conditions to america.' Now get out there, support your president, your congress and the supreme court and employ an illegal alien today.

I am counting on you to be a team player here hal.

Now put down those silly crickets and the thermometer and get to work man!

G.W.B.

WOW? You must be kidding.

Here's my "Elmer's" mobile rig circa 1958.

http://www.qsl.net/n7ws/w7uvr.jpg

Folding 2 el beam (later three elements) on 30' rotatable pneumatic
mast.

4-1000A high-level plate modulated (later SSB linear). "Pole-pig"
transformer, with extra leaf in the spring on that side.

5 KW generator (later 15KW)

Two bumper mounted, hat-loaded verticals with remotely tuned
vacuum-variable/rotary-inductor tuning.

2400. Calculating loss on a mismatched line

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-06 22:07:41 UTC
From: Owen <owen@no.where>
Message-ID: <e1loc1554j1hec26o62l5c7sn5ugublgrp@4ax.com>
Source record: 73766

Apparently, Michaels described in "Technical Correspondence" in QST NOV 1997 a method for calculating loss on a mismatched line.

I don't have the article, and haven't been able to find it on the net, so I am working from references to it that I have seen, mainly in Usenet.

Apparently, the method involves calculation of a factor (let's call it MR) as MR=|(Zl-Zo*)/(Zl+Zo)|, and the line loss between two points is given by 10*log((1-MR1**2)/(1-MR2**2)) where MR1 and MR2 are the values for MR at points 1 and 2.

I have compared the results of this on lines with Xo<0 and high VSWR, and the results are identical to calcuating the loss by subtraction of Real(VI*) at point 1 from Real(VI*) at point 2.

Has anyone a link to, or a reference to the derivation of the formula?

Owen

Sorry, that gives the additional loss "due to SWR" which has to be
added to the matched line loss to obtain the total loss between points
1 and 2.

Zl in the formulas is the impedance (V/I) at the point where MR is
calculated.

Well, Owen, you might take a look at Appendix 8 of Reflections 2, which can be found on my web site at w2du.com. Click on 'Read Appendices from Reflections 2', the click on Appendix 8. I think what you'll see there will be of interest.

Thanks Walt. I had a look at it, and although it doesn't state as
much, isn't it correct only for distortionless lines (Xo=0)?

2408. New program. Two SWR meters.

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-06 23:12:36 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <dahoh4kaa1@nwrdmz02.dmz.ncs.ea.ibs-infra.bt.com>
Source record: 73774

This program models the behaviour of a transmission line plus antenna. The line impedance can have any Zo. The antenna feedpoint impedance can be any value of R+jX. Line length can be any fraction and number of wavelengths. Line overall attenuation can be any value of dBs.

There is an SWR meter located at each end of the line. The meters also indicate the reflection coefficients at the locations. Meter Zo can be set equal to line Zo or to the standard 50 ohms.

Line input impedance can be observed to change versus line length in wave-lengths, line attenuation and antenna impedance. The transforming action of the line can be demonstrated. The smaller SWR and reflection coefficient at the transmitter end of the line can be seen. The exact increase in loss due to standing waves on the line is calculated.

The program can be used in practical applications and also for educational purposes. It is hoped it may prevent the outbreaks in violence which frequently occur in newsgroups about the meanings of SWR and the notions of reflected power.

Download program SWRARGUE from website below in a few seconds. File size = 41 Kbytes. Run immediately. No unzipping inconvenience.

Owen,

Your formula is too short to be anything but an approximation. It may
be a very good approximation. On the other hand it may contain
exactly the same errors as whatever you may have checked it against.

The exact formula is exceedingly involved and occupies about half a
dozen lines of source code in new program SWRARGUE which by
coincidence I have just placed in my website.

You can check your formula against my program. Let us know how you get
on.

Thank you for the clues. The 66' length and 10-40 M was very attractive.
This is for SWL only ! (apartment attached)

We HAVE an Ham Radio Supply branch store in O'do from whom i bought a
Grundig R350 a while back. their antennas were overkill for my
application and TOOOO BIG!

Had been using a vertical slinky but it really poopsout above 40M

I have calculated the loss using P=Real(V*I*) at the two points, and
it is long winded. Michaels approach produces the same result, and the
coding is more elegant, probably faster to calculate. He is a SK, so I
can't ask him, but in the hope that it is well known, someone might
know of the derivation.

Your calculator does not allow complex Zo does it? Doesn't that mean
it assumes a distortionless line. I am calculating loss in the general
case.

Thanks...

Owen

As I understand it, Owen, a line has to be lossless for Xo to be 0, while distortionless lines have loss but have equal series R and shunt G. All lines that I've measured have a small negative X, that would be zero if the line were lossless. So I'd have to say that the material in Appendix is is correct for standard lines. Distortionless lines are normally found only in long-distance phone lines used at voice frequencies, not RF. Or am I missing something?

Reg, the two SWR meters, one at each of the line, follows precisely the
method I presented in Appendix 8 of Reflections 2 to explain how to
determine the additional line attenuation attributed to SWR. Appendix 8 can
be found on my web site at w2du.com. Click on 'Read Appendices from
Reflections 2', then click on Appendix 8.

I think "Computation of Impedance and Efficiency of Transmission Line
with High Standing-Wave Ratio", W.W. Macalpine, Transactions of the
AIEE, vol. 72, pp 334-339; July, 1953 might be of interest to you.

The same reference is used as the basis for the section
"Transformation of Impedance on Lines With Highh SWR" in the ITT
handbook.

Walt, I learnt that a distortionless line is one where attenuation and
phase velocity are constant for all frequencies, and that requires
that R/XL=G/XC in the RLGC model of a lines characteristics, and the
result is that Zo is purely real.

A lossless line is a special case of a distortionless line.

If you like, I am saying your approach is valid for lossless lines, it
is also valid for all distortionless lines, but I think it is not
accurate for lines in the general case because it isn't correct if
Xo!=0.

My program assumes line Zo is purely resistive. But at HF it is
practically impossible to tell the difference in line loss between an
angle of 0 degrees and 1 degree which is the range of Zo angles
involved.

I have the exact formula for any line but its far too complicated to
write here.

I didn't use it in my program as it would have meant another input
value for no useful purpose.

Yes, I saw (and I think, understand) the formulas under the heading
"Power and Efficiency" in my ed #6 of the ITT H'book.

Not wanting to express the algorithm in pseudo code (AKA ugly ASCII
math) here, 'cos it *will* be unreadable, I have pasted the formula I
have worked up, and a plot of it in a particular scenario at
http://www.vk1od.net/temp/LineLoss.htm .

Given, that to support this, there is are functions for Gamma(load)
and Gamma(x), it is a whole bunch of code, and Michaels approach is
attractively simple, and it produces exactly the same answer on this
scenario.

Owen, if X = 0 there is no attenuation, but you're saying my material is
invalid if X is not 0? I'm sorry, but I'm confused.

Walt, I don't think that Xo=0 implies zero attenuation, but it is true
that if the line has zero attenuation that Xo=0.

I think the method in your appendix is true when Xo=0, and an
approximation where Xo!=0.

I have just added a function (DLoss) to calculate loss as per your
appendix to the graphic at http://www.vk1od.net/temp/LineLoss.htm ,
and it can be seen that in this (perhaps extreme) case, it is not a
very good approximation.

I also added the same calcs for f=100MHz and Zo is much closer to
real, and it can be seen the approximation is much closer.

In my first edition of "Paul and Nasar", p 335, dealing with lossy
transmission lines; there is a footnote as follows:

For the interested reader, a very thorough discussion of the derivation the
transmission-line equations is given in R. B. Adler, L. J. Chu, and R. M.
Fano , "Electromagnetic Energy Transmission and Radiation", Wiley, New York,
1960, chap. 9.

I have never seen the reference, so cannot comment, but may be available in
a university library. Wonder if that is the Fano in "Fano's limit".

73,

Frank

Sorry all,

The function for DLoss on the web page was for the additional loss due
to SWR. I have now added a term to the DLoss function to include the
matched line loss and updated the web page.

The outcome hasn't changed in that the two methods of calculating loss
only agree if Zo is real.

Or to be just a little crazy... but as they say, you don't have to be
crazy to be a ham, but it helps.

Field day activities were fun. Somehow replacing cubic metres of field
equipment with a shoebox sized "black box" that does 100W of SSB from
160m to 7ocm has eliminated much of the fun.

We are seduced by radios with lots of features in silicon, often
without much regard for how it performs as a receiver, things that we
can't fix, whether because of a lack of knowledge, test jigs,
alignment / diagnostic software or board rework equipment. We have
come a long way!

I have used some toggle switches as RF switches in the HF range in the past without problems but want to use one in a somewhat higher power application. Toggle switches generally are only rated at voltages such as 120VAC (50-60Hz assumed), 250VAC (50-60Hz again), or 30VDC. Looking at the specs for vacuum relays show that a current derating of ~3X when going from 60Hz to 30 MHz seems about average. Is there any reason why a similar derating would not apply to a mechanical toggle switch. E.g. would a miniture toggle switch rated at both 250VAC 2A and 120VAC 5A handle 100W at 28MHz (50 ohm impedance assumed)? I was not going to do any hot switching.

Something like that usually works for matched lines. Where I got into
trouble is trying to use toggle switches on ladder-line carrying an
SWR of 20:1. It fried an RS heavy duty toggle switch. You can avoid
such trouble by switching to knife switches with their wider spacings.

Walt,

As suggested, I looked up your paper in your website about "Additional power lost in trans-lines due to SWR."

It is applied only to coaxial lines, of course, because the usual SWR meter cannot be used on balanced twin lines. Actually it applies to all lines.

I think your calculating formula is an approximation. It is due to the SWR meter discarding all information about the PHASE ANGLE of reflections. ie., the angle of the reflection coefficient (Gamma) from which you have used to calculate SWR in your explanation.

Gamma has an angle which can lie in any of the four quadrants. Theoretically this cannot be neglected.

I can't prove the approximation because I havn't the mental energy to do the exact calculations involved.

For interest, my program SWRARGUE calculates the exact power lost in the line for any SWR for a given input power of 100 watts. Power lost is then a percentage of input power. Transmission efficiency then follows. Note that the internal resistance of the transmitter or conjugate matching is immaterial.

It does this by first of all calculating the input impedance of the line, when terminated with the antenna feedpoint impedance, in the form of Rin + jXin.

From the input power it then calculates the line input current and volts.

From normal transmission line formulae it then calculates line output current and volts.

It then calculates the power dissipated in the antenna input resistive component. This is the power radiated.

The difference between radiated power and 100 watts line input must be the power lost in the line. Line efficiency and the decibels follow.

The excess loss due to SWR is the difference between actual loss and the line's overall matched attenuation, which is an input to the program. Which, to me, appears to be an artificial way of looking at things and your approximation arises from it.

The way to prove the point is to calculate the excess loss due to SWR
your way and compare with the results from my program.

I wouldn't be surprised if there's no significant difference. The
matter about the imaginary meanings of SWR and confusing reflected
power is not worth the trouble of arguing about.

=======================================

On this subject the only hope of discovering the exact loss on a line
with SWR is to do an exact complex mathematical analyis for yourseslf
and hope you don't make any mistakes.

For starters, the calculated curves shown in ARRL publications over
the years, as plagiarised by the RSGB, are in error. But they are near
enough not to lose any sleep about.

Why the importance attatched to this line feature I can't imagine.

Reg.

Reg, my Appendix does not apply only to coaxial lines. Like you also said, it applies to all lines. Balanced twin lines also have SWR, as you already know, but my words didn't limit measurements of SWR only to coaxial lines. There are ways of measuring the SWR on open-wire lines other than instruments limited to use on coaxial lines.

> I think your calculating formula is an approximation. It is due to the
> SWR meter discarding all information about the PHASE ANGLE of
> reflections. ie., the angle of the reflection coefficient (Gamma) from
> which you have used to calculate SWR in your explanation.

No approximations at all, Reg. As you know, reflection is the cause of SWR, not the reverse. Further, the coefficient of the reflection that results in SWR is the magnitude of the complex value in polar form. Therefore the magnitude of the SWR is determined by the complex reflection coefficient, resulting in the correct value, not an approximation. The complex reflection coefficient can be used to determine the complex impedance. SWR simply lacks the angle of the polar information, and is thus unable to supply the required information to determine complex impedance. Thus the value of SWR does provide the polar magnitude of the complex reflection coefficient, not just the |rho| value.

> Gamma has an angle which can lie in any of the four quadrants.
> Theoretically this cannot be neglected.

And I submit, Reg, that although the numerical value of the angle is omitted, the effect of the angle has not been neglected.

> I can't prove the approximation because I havn't the mental energy to
> do the exact calculations involved.

I'm saving you the mental energy, Reg, because there are no approximations involved--the exact calculation has been made.

For interest, my program SWRARGUE calculates the exact power lost in
> the line for any SWR for a given input power of 100 watts. Power lost

> is then a percentage of input power. Transmission efficiency then
> follows. Note that the internal resistance of the transmitter or

I downloaded your SWRARGUE program, Reg, and ran it. The numbers using your program and those using my Appendix 8 are identical.

snip

> The excess loss due to SWR is the difference between actual loss and
> the line's overall matched attenuation, which is an input to the
> program. Which, to me, appears to be an artificial way of looking at
> things and your approximation arises from it.

As I said above, Reg, the values obtained using your program and those using my Appendix 8 are identical. My method does not reveal any approximate values, so it cannot be an artificial way of viewing the procedure.

> The way to prove the point is to calculate the excess loss due to SWR
> your way and compare with the results from my program.

As I just said, I have compared my results with those of your program and the resulting numbers are identical.

> I wouldn't be surprised if there's no significant difference. The
> matter about the imaginary meanings of SWR and confusing reflected
> power is not worth the trouble of arguing about.

Not only is there no significant difference, Reg, there is NO difference. Think about it.

Richard, I have an 18th edition, and the formula it gives does not factor in the angle of the reflection, and so is an approximation.

I don't know if that applies to the 19th edition.

Back to my original post, I was not in search of a formula for an exact solution, nor a reason to want an exact solution, but rather whether anyone has seen the derivation of Michaels formula quoted in QST Nov 97.

Thanks for your help.

Don't be fucking stupid. The fact that we are amateurs does not give us
a license to go out and be complete idiots when it comes to erecting
structures which endanger lives and property in the case of a collapse.
His installation is a textbook of how not to approach erecting a tower,
and several people already pointed out why. If he only spent a few hours
Googling for tower tips and reading the Rohn catalog, he could have
avoided at least the most blatant mistakes he made.

"It looks great"... Yes, I'm sure this is the primary concern of
structural engineers everywhere, that their projects "look great" in jpegs.

> and I will bet it will stand the test of time.

I will bet that if I kick a grizzly bear in the balls, I will stand the
test of time, too. The only question is how much time we're talking about.

> It is a shame that every user group on the internet has so many weenie pricks

It seems to me that the method requires that rho is not greater than
one (otherwise the denominator (1-rho2**2) becomes negative, which is
a nonsense). This hints that it does not apply in the general case
where rho *can* be greater than 1, and is therefore probably limited
to cases of distorionless line (Xo=0).

To avoid publishing "ugly" maths here, I have put a page up at
http://www.vk1od.net/temp/reflection.htm with a bunch of expressions
for conditions on the modelled line, including functions for power
flow at an arbitrary point, Loss calculated from powerflow at two
points and loss based on your loss formula + matched line loss.

The graphs show the loss from point x to the load, x is 0 at the load
and negative toward the source.

The algorithms produce quite different results. If I ignore Xo (ie
force Zo to be real), then both algorithms produce the same results.

Have I made a mistake in the maths, or in modelling the scenario?

Thanks for responding, Owen, but I'm going to be otherwise occupied until
Saturday, so the fact that I don't respond immediately doesn't mean that I'm
ignoring you.

Nice logic, albeit not much surprising in these "morality" driven times:
"liberal use of profanity" is of the same impact and scope as erecting
an unsafe tower.

However, let me rewrite my profanities for all of you who subscribe to
the notion that eradicating a few words will solve all the world's problems:

Don't be fucking stupid. ==> Don't be having sexual relations not so smart.

if I kick a grizzly bear in the balls ==> if I kick a grizzly bear in
the testicles

average dumbass ==> average dumb behind

I hope no one suffered any extensive trauma from reading my profanities.

2454. SWR losses in 300 ohm TV twinlead vs coax

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-08 02:18:12 UTC
From: Buck <iam@this.site>
Message-ID: <48nrc1lt2gp0v0lntelou088gd0v7j1co4@4ax.com>
Source record: 73720

I have installed a 135 foot dipole which I tune for all bands but 6
and 20 (I have dipoles cut for those bands.)

Well, one of the locals and I were discussing a loop antenna. He
insists that the loop is better fed with 65 feet of 75 ohm coax and
then 50 ohm coax to the tuner for the radio. I was saying there would
be less loss by using a 300 ohm twin lead since it was being tuned for
all the HF bands and 6 meters, with open wire or ladder line being
better options. He insists that if the loop is properly made, it is
better to feed it with the 75/50 combo which properly matches the
antenna.

any thoughts?

I guess then we are to conclude that you can not express outrage at a situation with out gutter language.

You Sir are the one with flawed logic, regardless of the perceived offense one sees in the construction of a tower, it conveys no license to assail the members of the group with gutter language.

Might I suggest a course in creative writing at your local adult education center? It may expand your vocabulary beyond the profane utterances we have seen so far.

The 75 ohm matching section is for a single frequency (narrow-banded).
On that single frequency, it is probably just as good as the twin lead
model. However, on other bands than the one for which it is designed,
it will probably not function as well as the twin lead model. Your
"local" just proves that a little knowledge is a dangerous thing.
Do you want a multi-band antenna or a narrow-banded single-band antenna?

>any thoughts?

I think that's going to depend very much indeed on the size of the
loop and on the band(s) on which you're trying to use it.

If I recall properly, a 1-wavelength resonant loop will have a
feedpoint Z of around 100 ohms. A quarter-wavelength section of
75-ohm coax will transform this down to something close to 50 ohms,
and you'll have a good match.

This specific case doesn't generalize, though. If you use the loop on
the second-harmonic band, its feedpoint impedance will be a higher (I
think), the "quarter-wavelength" 75-ohm section will now be about a
half-wavelength long and will mirror the feedpoint impedance to the
50/75-ohm junction. You'll see a higher SWR (maybe 2:1 or worse?) at
the junction and thus at the transmitter. Same problem, even moreso,
on higher-numbered harmonic bands. It'll likely be usable, but I'd
guess that losses may become significant depending on the coax type
and length.

On non-harmonically-related bands, the situation could be even worse
than that, with a very high or very reactive impedance at the
loop/75-ohm-junction point, and a high SWR and significant losses all
the way to your tuner.

65 feet of electrical length is roughly a quarter-wavelength at 80
meters, but that neglects the velocity factor of the cable. A setup
using this sort of matching arrangement with 65 physical feet of
75-ohm coax would behave somewhat differently depending on whether the
75-ohm coax was solid-dielectric or foam/air dielectric, due to the
difference in the velocity factors.

The number one fallacy in the Internet communication of any kind is the
assumption of certain posters that they are the official spokespersons
for everyone in the world. Hence "we".
Another fallacy is the projection of one's own morality standards onto
the entire world. Hence "gutter language".

> You Sir are the one with flawed logic, regardless of the perceived offense
> one sees in the construction of a tower, it conveys no license to assail the
> members of the group with gutter language.

One replies to a post in the style and the manner of the original
poster. I see his (anonymous to begin with) post as a clear assault on
everyone's intelligence and I reply accordingly.

> Might I suggest a course in creative writing at your local adult education
> center? It may expand your vocabulary beyond the profane utterances we have
> seen so far.

What makes you think that using "gutter language" somehow automatically
decreases one's vocabulary? Perhaps it is no coincidence that most of
the morality police today are strong proponents of this modern day
phrenology equivalent?

Your OO status does not extend to the Internet, Fred. Clean up the ham
bands from bad ops of all kind and leave the newsgroups alone.

He's confusing the operation of a single band loop, to
your planned all band operation. If single band, I would
prefer his method. If all band, I would prefer yours. The only
downside
to the 300 ohm line is it gets pretty lossy when wet. But 450 ladder
line with
"windows" would cure most of that problem. On the upper freq's
with a high SWR, the 300 ohm line would have less loss than coax.
On VHF/UHF, the difference is drastic. If you feed a TV antenna with
rg-6
coax and balun, you will have a good bit more loss than using 300 ohm
line.
On UHF the difference will be fairly huge. But expect a blackout when
it
rains hard. The local ATV machine would turn to snow. Once the rain
quit, it would gradually come back. :/ If you are working all bands,
and
using a tuner, there is no reason whatsoever to tune or match the
antenna to
the line. Waste of time...

Anyone who would fault your tower installation has a serious case of
"penis
envy". It looks great and I will bet it will stand the test of time. It
is a
shame that every user group on the internet has so many weenie pricks
lurking trying to find fault with every post. I'd be proud of a tower
like
that so don't let the idiots detract from it.

I haven't faulted it cuz I haven't had time to even look at it.
But if this many people are ragging on it, I'm sure they have
a pretty good reason. Just the "sins" I've read about are
pretty serious. And no, I don't have pecker envy...I have two
towers. One, a stout tilt/crank. If I were to envy a tower, I would
envy one worth envying...
There are some lurking here that have towers that would
make his look like an overgrown tinker toy contraption.
He may be a bit put out that many are ragging his tower,
but if I were he, I would pay attention. Most comments I see
from the raggers look to be on the money. You don't take
chanced with towers. That sucker can fall *through* a
house, and kill anyone it hits. Don't believe me? Check the
stats on hurricane deaths. Many are killed by trees falling
through their houses. That tower is quite capable of thinking
it's a tree. It might not be green and have pretty leaves, but it will

still kill you deader than a squashed june bug.

2466. Really low SWRs but is it worth trimming the antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-08 11:04:02 UTC
From: Blue Dawg <thecowboyace@yahoo.com>
Message-ID: <1120820642.403459.107860@g49g2000cwa.googlegroups.com>
Source record: 73632

I am running a President Grant am/usb/lsb and on Channel 1 the SWR is 1:0.08, on Channel 40 it is 1:1.45 and on Channel 19 it is 1:1.09. It really isn't worth doing an adjustment on this antenna setup is there? The antenna is a single Yagi beam made up of two Tram Penetrators (Monkey Made's). I think that it is sold as a 1/2 wave antenna and have heard that it is a 5/8 wave. This antenna can be set for 10 meter usage also. It really looks weird up there without a reflector on it. I may put a reflector on it but am stumped as to length of the reflector (ging to be made of 1/2" electrical conduit). I can't find the formula for the length taking into consideration of the diameter of the reflector. I believe that the 'stand-by' one should use 468/f. Using 27.185 (Chl 19) the length should be 17.22 feet. Only thing is the length of the driven element is less than 12' because of the antennas having the centerload coil in them.

What do you think?

2467. Re: Really low SWRs but is it worth trimming the antenna

yes, keep trimming until the swr is 1:1.0001 or less across all the channels. anything higher than that will absolutely fry your transmitter and cause you to go sterile because of all the reflected power leaking out of your rig. electrical conduit is such a great conductor that it will help the swr also by sucking all the power that would have been reflected back out of the coax, i would recommend 17.22329 feet, plus or minus .00001, the tolerance is very important, a hair too long and it won't reflect properly, too short and it will act as a director and totally reverse the pattern.

My HF9V has withstood Iowa and PA winds, both ground-mounted and
elevated without a single problem. The antenna can be guyed, however, if
you feel it necessary. The directions show the placement of guys on the
mast. It's important to get the proper placement so winds don't do any
damage if it's guyed too high or too low.

If you don't have the instructions, you can download them at

PS. The loop we were discussing was cut for 80 meters and was to be
used with a tuner to tune all HF bands.

Thanks for your comments. I purchased a new HF6V, and the instructions do
mention keeping the angle about 45�. I plan to install it without guys, but
I wanted to see if someone had some strong advice to the contrary.

Ignore Dave's sarcastic statement. The antenna will work very well as
is. It could be trimmed to be a little better, but you and your radio
will not notice any difference.

If it were my antenna, I would leave it up and take the time either
enjoying the radio or studying for an Amateur Radio Licenses. :)

(Had to put a plug in there.)

73 and good luck

Walt, my suspicion about approximation, based only on appearance, was
not justified.

So your "two SWR meter" formula and my program agree exactly.
Therefore your formula must be correct. ;o)

Thanks for your trouble to sort things out for me.

Reg, G4FGQ

"Antennas" by Kraus & Marhefka:
http://www.amazon.com/exec/obidos/tg/detail/-/0072321032/qid=1120836458/sr=8-1/ref=pd_bbs_ur_1/103-0117018-4818221?v=glance&s=books&n=507846

It may well be the last edition given that Dr. Kraus died last year.

The usual "classics" also include Balanis's "Antenna Theory: Analysis and Design" and Stutzman & Thiele's, "Antenna Theory and Design." IMO, Kraus is a better place to start in that the math is somewhat simpler and Kraus was a very "applied" sort of guy.

Blue Dawg wrote:
"What do you think?"

I gather Blue Dawg has a 1/2-wave dipole made from (2) 1/4-wave coil-loaded whips. That works. The coils are necessary because the whips are too short without them.

At 27.185 MHz, WL=11.035 meters=36.20 ft.

Kraus proposes a "modern version" of the Yagi-Uda antenna on page 258 of his 2002, 3rd edition of "Antennas".

The reflector is spaced 1/4-WL behind the radiator. It could be closer for more gain but this would make dimensions of the array more critical, and the improvement in pattern is probably not worth it.

The reflector is 1.03 x the radiator length to get the required inductive phase lag required of a reflector.

Length of the reflector is 0.475 WL. Length of the radiator is 0.46 WL. Lengths of elements shrink as they get fatter and Kraus assumes thin wires. They are also shorter with loading coils. Bandwidth improves with fat elements and worsens with loading coils. The elements are shorter than 1/2-WL due to "end effects".

The length of a thin non-loaded radiator for 11.35-mtr operation is 5.22 m = 17.13 ft.

The length of a thin non-loaded reflector for 11.35-mtr operation is 5.39 m = 17.7 ft.

Should you trim the antenna to optimize it? Probably not unless performance is at least 1 dB less than expected.

Best regards, Richard Harrison, KB5WZI

Hi OM,

It's going to look quite odd with that conduit (no physical strength
to speak of) drooping in the wind. And it would look odd if it didn't
droop, being so much bigger:

> I can't find
>the formula for the length taking into consideration of the diameter of
>the reflector. I believe that the 'stand-by' one should use 468/f.

Well ï¿½

The formula neither takes into effect the larger diameter of your
"wire" reflector, nor its reflector size (which would be approx 5%
larger than you might expect).

>Using 27.185 (Chl 19) the length should be 17.22 feet. Only thing is
>the length of the driven element is less than 12' because of the
>antennas having the centerload coil in them.

And your point is?

If you want an expected outcome, you do what you have to do and get on
with it. In your case, if you are seeking elegance you would then buy
two more units, clamp them base-to-base, put them about a 20th wave
behind the first two, and tune the reflector (make it bigger) by that
same roughly 5%.

If you haven't already noticed all the loose terms (about,
roughly,...) then you may think that was the end of it. But no,
there's more! How much more depends on how deep you research these
size and distance correlations, or simply take someone's word for it
and build an aircooled dummy load.

Hi OM,

If you may notice the disparity between my post in this particular and
KB5WZI, Richard Harrison's (which is far better researched) then you
may note also his warning for element diameter (your conduit is not
"thin" by any stretch of the imagination to suit precision and text
book formulas).

Having read this thread from the beginning I feel compelled to comment myself at this time.

A couple of weeks ago the area I live in was subjected to some high winds. How high I don't know but my neighbor across the street had to pick a very large tree out if his attic. How large you ask? Glad you asked. I measured the circumfrence at a point that would have been about 5 ft above ground. It measured 87 inches. Now that's one large tree. What happened? The roots snapped off at ground level. So do not trust a living thing to hold anything.

Where are these Hundreds of Thousands coming from? The defeat of the Iraqi Army during Desert Storm. That was a conflict started by the Iraqi President. The US President lead the army that defeated him. The majority of the casualties suffered during the current action have been the result a deliberate campaign by those opposed to the Iraqi people guiding their own destiny. To say otherwise is to devalue the lives lost in this action. I look foreword to the day that all non Iraqi military personnel can go home in peace and with honor.

Walt, it has just occurred to me that I am using the "actual" Zo, not
the nominal Zo, and I think your rho calc is based on the nominal Zo,
as it will be measured with an instrument presumably calibrated for
nominal Zo.

I have compared the loss calculated by your method (with rho based on
nominal Zo, Zo=Ro+j0) and my method and they are very similar (though
not the same). I have added a function to calculate the loss using
your formula based on nominal Zo and plotted it, along with the
difference to the power based loss calc. They are at
http://www.vk1od.net/temp/reflection.htm .

If your method is based on nominal Zo, rather than the actual Zo, it
is likely to be an approximation, though on this example, it is pretty
close and probably is quite adequate for most practical lines at HF
and above. (The error increases as frequency is reduced (Zo departs
more from nominal Zo).)

Having resolved the apparent inconsistency... I am still in search of
a derivation of the Michaels formula.

I have no problem loading up (Linear, with Pi network) my 75 m loop on 18
MHz, but performance wise it is a dog. Much inferior to the 18 MHz dipole,
which is not as high as the top of the loop. You might want to run EZNEC on
this. Received signal strtength on other bands is WAY down.. Works fine on
75DX, not so hot for locals.

2490. 20m Halfwave Vertical QST article

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-09 02:17:43 UTC
From: "Michael St. Angelo" <mstangelo@comcast.net>
Message-ID: <GPudnSRA6NEjrlLfRVn-iQ@comcast.com>
Source record: 73656

QST had an article about a 20 meter halfwave vertical that was end fed with
a coaxial matching section for 50 ohm feed.
It was essentially a j-pole constructed from coax. It was in a 1980-early
1990 issue of QST. Does anyone recall the article
and the issue?

Thanks,

Mike N2MS

I have do not have guys on the HF6V I own and have had no problems at all. WE had sustanied winds of almost 60mph this winter and no problem at all.

Do take the time though if you have not already and add a few radials. Cut you lawn real short,, lay down several radials, pull them taught and then stake them in the ground with ground cloth staples (garden center) The grass will grow right up aroound them and they will "disapear" into the ground. Huge difference in performance.

Actually, just did a quick webbing and found enough to
realise that the claims are founded upon feet of clay.....

1. You do not separately excite the E and H fields because
if you excite an E field, you get a corresponding H field, and vice-versa,
even if it is your intention to excite separately.

2. The differential forms of Maxwell describe the fields at _EVERY_
infinitesimal point and there is no way that the attempt to excite two
separate fields from two separate mechanical contrivances will result
in registration at every single point. Indeed, it is doubtful that
registration
will be achieved at all at any infinitesimal point. In any case, as in (1)
above,
your E field will have its H, and your H field will have its E field
already.

3. In the accepted equations describing the generated field, radiation comes
only
from accelerating charges. Thus the capacitive elements of the CFA will
create the near field (decaying as 1/(r^2)) but not any radiated field
(decaying as 1/r). I wonder if the measurements resulting in the claims
for the CFA were made in the near field?

I wonder if the whole thing is intended as an elaborate hoax, and that the
authors, in their original paper in Wireless World, relied on the fact that
most readers' eyes would glaze over when faced with the maths of vector
fields? (Remember, that in this NG we've had someone who boasts of
two degrees, one in maths and the other in electronics, stating that
e^(-jwt)
is a function that decreases with increasing time, thus indicating that the
awarding of a degree together with the professing of mathematical
equations is no guarantee of competence!)

I suggest http://farside.ph.utexas.edu/teaching/em1/lectures/node53.html etc
as a good revising/learning/debunking cookbook. (Don't start from node 53!)

I've seen just a dropped gin pole alone almost go through the
roof of a house. It left a hole. A light aluminum tower might
be stopped by a house, but I wouldn't want to take my chances
with a heavy steel tower. He might get lucky and have it last a
few years. But one bad storm, and it could be a problem.
Nearly worse is a tower that crumpled over midway due to snapped
guys, and then you have the fun of trying to get the mess back
on the ground without killing someone. MK

Sounds like "The Half-Wave Vertical" by John Belrose, VE2CV in September
1981 _Ham Radio_. It's a sleeve dipole, like the antenna I've heard
called a "bazooka" when used at VHF. That used to be a common type of
VHF/UHF antenna although I don't see many around these days.

Your first point does in fact point to the anomaly regarding points in
your second point, and you have therefore pointed up the answer to
your own point. As you clearly have not thought this point through, I
pointedly leave its discovery as an exercise for you. While you
continue to struggle for technical excellence, doing this should help
point you to the requirements demanded of scientific thinking, and the
possibility of also taking your first tentative steps in that
discipline. Further, as a guide, scientists do not use personal
pronouns in their formal writings, so you might also like to rewrite
your article in such a manner.

I do plan to add a fair number of guys, and will be installing them just as you have suggested. I do have a question about driving the 1 1/8" mounting tube into the earth. The directions give a warning about splitting the plastic insert and suggest placing a piece of wood on top of the tube and then hammer on the wood. The soil here is clay, and the ground is quite dry, at the present time. Do you, or anyone else, have any suggestions about driving the tube into the ground. Should I drive a wooden stake first to form a hole, remove the stake, and then drive the tube into the hole left by the stake?

I's suggest you take a few days and water the area first, you can use
a 'starter hole' approach also. Drive a stake in and withdraw then
over the course of a day fill that hole with water and allow it to
seep in then water again. You don't want to go too deep with your
'starter hole' though - just enough to hold some water.

This may be fine for some amateurs. But what about the people in
southern England where the present water shortage will cause the
goverment to introduce compulsory metering of domestic water supplies.
It's something to do with Earth warming, man-made climatic
disturbance, and the price of a glass of clean drinking water in
London.

Use GRAY water. That's the water from the sink, bath tub etc. This will
ease the load on the waste water treatment plant and allow you to soak
the ground at the same time. A little more work but it can be worth it.

You're right, mine was a Hudson with a loop DF and Hallicrafters SX-27 and SX-28 receivers. There had to be a somewhat intelligent brain connecting the DF to the steering wheel. Did you drive your car during the time the NDO and RID existed? I was a charter member beginning in 1940. My wife-to-be disseminated more than 500 invitations to join from her FCC office in Washington as an assistant to George E. Sterling, then Chief Engineer of the FCC.

If well-known Radioman/FCC Agent is so well known how come I don't know him? I can't believe you're gonna give away any Home Security secrets by tossing your anonomity cloak. How about coming clean with us?

You just don't know any of the Old Gang from the Left Coast, Region X,
and Alaska, that's all. and it was a Van, Creme and Brown, with local
State Plates, or a dark blue Stationwagon, dark tinted windows, with no
backseat and a pile of receivers. I once got myself in trouble by
calling it the SolsbyMobile..... Oh well, that was then.....and this is
now....

Here is the NIST WWV web page that Mac, N8TT referenced !
http://tf.nist.gov/timefreq/stations/wwv.html
WWV Antennas

The WWV antennas are half-wave vertical antennas that radiate
omnidirectional patterns. There are actually 5 antennas at the station site,
one for each frequency. Each antenna is connected to a single transmitter
using a rigid coaxial line, and the site is designed so that no two coaxial
lines cross. Each antenna is mounted on a tower that is approximately one
half-wavelength tall. The tallest tower, for 2.5 MHz, is about 60 m tall.
The shortest tower, for 20 MHz, is about 7.5 m tall. The top half of each
antenna is a quarter-wavelength radiating element. The bottom half of each
antenna consists of 9 quarter-wavelength wires that connect to the center of
the tower and slope downwards to the ground at a 45 degree angle. This
sloping skirt functions as the lower half of the radiating system and also
guys the antenna.

From my own experience (water problems aside) use a smaller pipe to drive a pilot hole. If your ground mount is 1 1/8", use either a 3/4, or at the most, 7/8" pipe to make a pilot hole. I tried using 1 1/8", and ended up with quite a bit of "slop". 3/4" seemed to yield the best results for me. Leaves enough earth to firmly hold the base, yet makes it very easy to install without beating the heck out of the base Itself!

Subject: Re: Calculating loss on a mismatched line

Hi Owen,

I'm trying to understand your Mathcad presentations, but I've run into some roadblocks concerning terminology, some of which I'm not familiar with. I confess my questions prove my ignorance, but that's ok if one's trying to learn. However, I was using nominal Zo.

First, Xo!=0. I don't know what this means.
Second, what does MML stand for in English?
Third, in 'functions for V, I, Z, etc at z'. Where is 'z'? I cannot find any reference to it.
Fourth, 'exp'. Exponent? If so, of what? e?
Fifth, I understand 'x' as distance along the line from the termination, but what is 'y'?
Sixth, what is AppLoss? Approximate? Apparent? Applied?
Seventh, 'DLoss'. What is 'D'? Dielectric? Again, what is the 'y' term? An ordinate value?
Eighth, in the LineLoss(x,y) = 10log... the identical right-hand terms in both numerator and denominator, the identical functions of 'e^^ x e^^. what is the meaning of the bar above the second appearance of 'e'? And above gamma(x)?

I want to understand your math presentation, Owen, especially when I see that Loss(x,0 - W2DUloss(x,0) is so small I want to understand what makes the difference. So I'd appreciate it if you'd set me straight on the points I made above.

Not the first time the CFA has been discussed here. The consensus is that
it is nonsense. Belrose has probably done the most rigorous investigation.
See the paper at http://download.antennex.com/shack/Jun00/paperdavos.pdf

I wonder who it was that is not familiar with Euler's formula.

>learn. However, I was using nominal Zo.

Not at all, you are far more eminent that I on this topic, and I
appreciate your review. I am learning from all this.

Apologies for the difficulty in understanding my notation. Some of it
breaks into psuedo programming code.
>
>First, Xo!=0. I don't know what this means.

Not equals.

>Second, what does MML stand for in English?

MLL? Matched Line Loss (dB/m)

>Third, in 'functions for V, I, Z, etc at z'. Where is 'z'? I cannot find any
>reference to it.

These quantities are a function of z, where z is a position on the
line. The convention that I have used for displacement is that it is
negative towards the generator. When it matters, displacement is in
metres. The z is just used in definition of some functions in Matchcad
(where you see :=), I have used x for position variable in the graphs.

>Fourth, 'exp'. Exponent? If so, of what? e?

exp(x) is e to the power of x (For clarity, I shouldn't have written
it that way, it works, but Mathcad understands the meaning of e
superscript x as e to the power of x, as you will see in some of the
expressions, and it is easier to read.)

>Fifth, I understand 'x' as distance along the line from the termination, but
>what is 'y'?

In some of the functions, I have written them to calculate some
quantity between two arbitrary points x and y. They are used in the
definition of fuctions (where you see :=). Most of the graphs use 0
for y so they are plotted wrt the load position

>Sixth, what is AppLoss? Approximate? Apparent? Applied?

Approximate Loss, and it was incorrectly based on Zo rather than
nominal Zo.

>Seventh, 'DLoss'. What is 'D'? Dielectric? Again, what is the 'y' term? An
>ordinate value?

DLoss was equivalent to AppLoss.

>Eighth, in the LineLoss(x,y) = 10log... the identical right-hand terms in
>both numerator and denominator, the identical functions of 'e^^ x e^^. what
>is the meaning of the bar above the second appearance of 'e'? And above
>gamma(x)?

The bar above the variable is the complex conjugate operator.

>
>I want to understand your math presentation, Owen, especially when I see
>that Loss(x,0 - W2DUloss(x,0) is so small I want to understand what makes
>the difference. So I'd appreciate it if you'd set me straight on the points
>I made above.

Walt, in the models at http://www.vk1od.net/temp/LineLoss.htm , I now
know why there is such a gap between DLoss and LineLoss. You will
recognise AppLoss / DLoss is your Appendix 8 expression, but my rho
function was based on the modelled complex value of Zo (characteristic
impedance), not the nominal value of Zo.

In the second lot at http://www.vk1od.net/temp/reflection.htm ,
AppLoss is equivalent to DLoss and it is based on nominal Zo, W2DULoss
you will see calculates the rho term (though not identified) using
nominal Ro.

Comparing the results with loss calcuated from P(x)/P(y) (the ratio of
the real power at points x and y), the conclusion is that using your
expression with actual Zo is not at all accurate, using it with
nominal Zo is very close. If I force Zo to be real for all modelling,
the results of all methods is exactly the same (within rounding errors
of the order of 10 to the power of -14)

Some of your questions are just about the Mathcad notation (though
that is not too dissimilar to normal handwritten math notation), but
some of it is my expression and usage. Again my apologies for
confusing with too little explanation. I appreciate your review and
comments Walt.

The bottom half of each
antenna consists of 9 quarter-wavelength wires that connect to the
center of
the tower and slope downwards to the ground at a 45 degree angle.

Sure, thats a "1/2 wave" antenna, but I would always consider that
a ground plane, rather than 1/2 wave vertical. It's got sloping
radials.
Same thing I used to run on 40m. I always called it a 1/4 wave ground
plane... MK

End feeding seems more difficult than center feeding.

Fairly easy. I always preferred the "gamma loop" type
matching device. On a low freq antenna, that loop could get a
bit large. On 20m, a 18-22 inch single turn loop would match it no
problem.
maybe less than that, cuz using the "standard" 22 inch loop for 20m,
you will usually tap around the mid point of the coil. So the coil
could
be shrunk down, to use more of it. I always used lengths of coax for
caps
if needed. "open stub" 100-120 pf is a good value for 20m.
You can also use a regular coil to match, but my gut feeling is the
single turn coil is a bit more efficient. I've never actually compared
though...
BTW...I consider WWV's antennas to be 1/4 wave ground planes being they
have elevated sloping 1/4 wave radials.
MK

One of my purposes in scraping off the rust from 34 years'
of unused E-M theory was specifically so that I could evaluate
the claims made for the CFA.

I was intrigued by the claims but at no times taken in by them.

But yes - I exposed my ignorance but not any weakness, but there is never
any
problem with such exposure if it is done in an open spirit of eagerness to
learn!

Hank, those general riders are expensive, and no, I don't have one. OTOH, I am not erecting a 75' tower, made with two dissimilar structural systems, joined together by amateur engineering and welding, a very minimal concrete base, and held in place with guy wires running to nearby trees and an illegal encroachment onto someone else's property. The OP wanted our opinion of his efforts; he got 'em. The extent of my insurance coverage has absolutely no bearing on the subject of AD5TH's tower project.

When radials are in the same plane, they don't radiate a significant amount. But when slanted downward, they do, pretty much the same as a conical element of the same outside dimensions. You can call a quarter wave vertical with sloping radials a "quarter wave ground plane" if you like, but unlike one with horizontal radials, the radiating portion is longer than a quarter wavelength.

In the case of the antenna being described, the upper radiating part of the dipole is a quarter wavelength and the lower part is about 0.7 times a quarter wavelength but effectively large diameter.

We have to get over the notion that calling some part of the antenna structure "ground" gives it some kind of special properties. It doesn't.

I admit I have only read the first few and the last post on this subject, but I just have to offer my opinions....

This is Amateur Radio. If the insurance companies and the politicians had their ways, we probably would not do much of any of this.

Here is a fellow who has takes his own unique circumstances and put up an experimental antenna support. He has chosen to accept the responsibility of haven chosen to do things differently. He has not done it the way I would have but only time will tell if he has fulfilled the structural requirements.

I have been down my own path on towers since the early 1960's and experienced two failures. It never occurred to me to call the insurance company. I always made certain that the mess stayed within the confines of my property.

Every tower project I have done has had at least one significant aspect that could be improved upon.

The only problems I see with using a tree as a guy point is that it moves a little and you have to take care to not kill the tree. Dead trees are unreliable.

In a lot of neighborhoods, land use is negotiable. Out here in the country I have come to accept that a few cows in the yard are something that happens from time to time. What constitutes encroachment is in the eye of the beholder...

I have always wondered about the accepted practice of putting up a 60 foot tower of all the same size sections. It seems to me that the top half or at least third would be better if it were lighter. It certainly is not going to see the same stresses as the lower components.

AD5TH lives in an area that sees some high winds, I hope this bad experience with the nay sayers does not keep him from sharing his experiences in the future.

Post Hole/fencing Borer comes to mind or depending on your current soil condition you could use a hose pipe with a tube inserted in the tip and bore a hole that way, albeit fairly high pressure is needed, but that could be achieved with a pressure washer. As you start off your bound to be soaked a bit, but as you [bore deeper] push/ pull the nozzle out of the hole so that excess soil/clay can be removed by the water, bore down to your required depth, insert pole and back fill with sand or tamp down soil sides. This is also one way to ensure you can get a decent enough hole, deep enough to insert a earth stake. Your idea of utilising a hole by driving in a stake would no doubt give you problems extracting it back out again as I assume that you would be requiring a depth of about 900mm? Dave d:-)

Hi Danny, your question reminds me of the 4-year old in a restaurant, went to find the rest room, then came back and told his mother he couldn' find it. So she went with him and discovered the reason he couldn't find it was because he had his underpants on backward.

Walt

The third edition of Antennas (recommended by Joel Kolstad) is certainly mandatory for study. Note that a paperback edition exists that costs much less than the hardback edition. The third edition is rather directed towards specific antennas (or classes of antennas) with plenty of examples and problems.

Do look for the first edition of Antennas by Professor Kraus (published in 1950). In my prejudiced opinion, since I studied under Professor Kraus, the first edition is a key text to antenna theory.

One should also have the ARRL's antenna book - relatively low cost and a wealth of practical information.

Kraus third, an HP calculator, and diligent working of the examples in the third edition will provide a real education about antennas and their environment.

Go for it! 73 Mac N8TT

The only thing I had on hand was some square cross-sectional hard wood stake. The cross-sectional diagonal length was about 3/4 of the Butternut mounting tube diameter. I have clay soil and we are in the middle of a drought, so I used plenty of water and each time went an inch or two deeper. Driving the mounting tube was quite easy, and the plumb is quite good.

The tube is now in the ground and secured to a DX Engineering stainless ground plane radial plate. http://dxengineering.com/

I think it was Bob Pease of National Semiconductor who commented along
the lines of "You may be able to trust your mother. If you're
extremely lucky you may be able to trust your government. You can't
trust your ground."

Or, in the short form, "There is no ground". At least, not as a
single, uniform entity with constant (and special) properties.

Dear John Gotwals (N9JG ?):
Great picture! Unfortunately, it is accompanied by a lot of spam, some
of which I may need to reboot to get rid of.

Please describe the white, solid tube. Does it go into the ground? Did
the large U-bolt and the plastic wedges come with the kit? Is the tubular,
metal sleeve a splice?

Interesting set up. Let us know how things progress.

Source record: 73615

We have to get over the notion that calling some part of the antenna
structure "ground" gives it some kind of special properties. It
doesn't.

Never said it did. But I still consider it a ground plane... :/
Or at least more of a ground plane, than a straight 1/2 wave.
Note the "VHFGP" in eznec, or elnec. It's noted as a "ground plane"
and is almost exactly the same antenna as WWV's versions.
Same 45 degree slope with the radials.
I do agree about the rest though.
BTW, when comparing a model of a "flat radial" GP, and one with
sloped radials, there looks to be an increase of current from the
radials,
but it's not huge. I think you need to get a pretty steep angle going
for the
cancellation effects to really disappear. In comparing the two on 10m,
at
40 ft at the base, the difference in gain between the two is very
small.
About a 1/10 a db or so... Where I show the straight 1/2 wave to be
appx .6 to .7 db better than the 1/4 GP's. Sloped radials, or straight.

Tends to make me think the 45 degree sloped version still acts a bit
more
like a usual flat GP, than the straight 1/2 wave. I think if you get
to 20 degrees
or less, then yes, it starts thinking it's more a straight vertical.
Of course, in the real world you would probably be hard pressed to tell
a
difference between any of them. MK

"... NEVER BEEN ARMED ..."! Is that REALLY TRUE ?

If I recall history lessons regarding ANGLO-SAXON conflicts over the past 1000 years, I seem to recall that many armies were 'raised' in the Isles and the people provided their own weapons.

Only after the establishment of a solid Monarchy were the citizens disarmed. [Power consolidating control of Power].

Is my understanding of history wrong ?

Source record: 73622

I would have liked to have attached the picture to my initial posting, but since this is not a binaries newsgroup, I abstained. I do not yet have a website, so this seemed the best way to make the picture available.

The Butternut HF6V is ground mounted by inserting a 1-1/8" X 24" tube (tube A) into the ground to a depth of approximately 21" with about 3" of the tubing above ground. Tube A has a fiberglass insulator inserted in the upper portion of the tube, and in addition to serving as an insulator, it is used as the support for the next antenna tube (tube B). According to the directions, the upper end of the insulator should be about 7" above ground.

There are no plastic wedges, but I did clamp tube A to the DX Engineering stainless radial plate which included a wedge made from light metal, probably cast or forged aluminum. This wedge and a stainless u-bolt are used to make an electrical and mechanical attachment between Tube A and the stainless radial plate.

I hope I have answered your questions,
John, N9JG

Um, a little. There's been a solid monarchy in England, at least, for about
1200 years.

Guns aren't an issue here. We're not allowed to have them. Nobody much (as
in about 90% of the population) cares. We care about things you folks have
never even heard about instead (fancy an ID card?)

Here endeth the second lesson.

From: "J. Mc Laughlin" <jcm@power-net.net>
Message-ID: <11d3bgi9lrmm832@corp.supernews.com>
Source record: 73624

Dear John:

Indeed you have answered my questions. I also re-read the manual on the manufacturer's site. The full nature of "Tube A with insulator" is not clear from the manual.

Here is my read-back: "Tube A with insulator" is cylindrical, has a diameter of 1.125 inches, a nominal overall length of two feet, and at the end of "A" that is expected to be above ground is found a fiberglass solid rod that is attached to the bottom part of "A" (composed of an unknown substance) with a metal sleeve having an attachment bolt extending radially therefrom. Do I have it?

My curiosity is driven by an interest to use one of these antennas as a receiving antenna at the end of a very long piece of coax. From what you have taught me, the bottom end of "A" probably should go into a cylindrical concrete foundation. (Wind here is unattenuated by trees.) I had been under the impression that the "bottom" of this antenna was to be clamped to a pole that is driven (or set) into the ground.

For quite a different reason than learning the nature of the "bottom" of the antenna, when you have the antenna working, please estimate the inside diameter of a hollow cylindrical plastic tube that will be able fully to enclose the antenna (as if the tube was a radome). I have a colleague who is thinking of a "flag pole."

From DXEngineering and your comments, I now understand the wedges.

Thank you for your assistance.

The spring and damper can be exactly model as an electrical analog; as can virtually any physical system. As a reference refer to "Dynamics of Physical Circuits and Systems", by Lindsay and Katz at Concordia University, Montreal. ISBN 0-916460-21-5 published by Matrix of Beaverton OR.

Wow! Check your history. Once it was a requirement for persons in England
to be armed. Practice was also compulsory.

It is true, and always has been true, that only when the state is not
afraid of its armed populous that you have citizens rather than mere
subjects.

Respectfully, Mac N8TT

Take a closer look at his photos !

Turnbuckels are not secured, they can work loose and cause failure.

Inadaquate ground wires from guy cables to ground rods.
The trees or light pole will explode is the cables take a hit.
Same for the tower ground wires, insufficient not to NEC specs.

Trees have roots to hold them in the dirt, telco poles do not.

Insufficient support posts in a few feet of dirt concrete filled pipes.
No substitute for cubic yards of concrete and or rebar.

Tower sections have already rusted, most likly internal rusting
as well.

Metal banding will damage the tree trunks, tree will be
susceptiable to disease and insect damage.

Nothing to be envious about this setup.

'structural integrity has not been established'

I'm that idiot. Actually, one of the very many. The equations for the two systems are identical.

Roy Lewallen, W7EL, ROW, ASI
(Reg's Old Wife and now Aero Spike's Idiot. The titles just keep accumulating. Of course I'm also a proud member of the OFC.)

You can't download it. First go to http://eznec.com/eznecpro.htm and read the "Additional EZNEC/4 Information" section. Then after you've obtained the required NEC-4 license see http://eznec.com/ordering.htm for ordering information.

I'm afraid Lawrence Livermore will need more of a name than "zzl". And so will I.

Roy Lewallen, W7EL

Of course, I should have mentioned a mass/spring/damper (equivalent to capacitor/inductor/resistor), not just spring/damper. I think the only physical system that can not be entirely modeled as an electrical analog is a thermal system; which has no inductor equivalent.

Frank

Oops, I stand corrected -- thanks, Frank. Once again I read too hastily. A *mass*/spring combination mimics an inductor/capacitor, of course. A damper adds resistance. So a spring/damper combination would act more like an RC or RL circuit, but with a little stray L or C from the spring's mass.

Hope I don't have to give up my new title. Titles really impress folks in some parts of the world.

Just try to imagine what you bloody 'ole Brits could have accomplished
around 1200 if you'd only had the tremendously high voltages achieved in the
near field of a CFA antenna to hurl at the enemy.

No problem Roy. To be exact a mass is equivalent to a capacitor.
As in Newton's 2nd law: f = m*dv/dt, and its electrical analog
i = c*dv/dt, where "v" refers to velocity in the mechanical case,
and voltage in the electrical. I think this qualifies me to place the
letters "ASI" after my name. Well; I must admit I took a quick
look at my physical systems text book, so hope it does not
disqualify me.

2578. Re: Butternut HF6V mounting tube with SS radial plate

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-11 02:29:35 UTC
From: John Gotwals <john@gotwals.xremovey.com>
Message-ID: <daslifldg1@mailhub227.itcs.purdue.edu>
Source record: 73544

A plastic rod has been partially inserted into tube A (to a depth of perhaps 6") at the end which is above ground. Tube A and the rod have been drilled at right angles to their axes of symmetry, and a screw has been inserted into the hole, and where the screw protrudes on the opposite side of tube A, a nut has been attached and tightened. When the antenna is constructed, this screw will serve as the junction for one end of a base matching coil (Coil Q) and for the shield from a short length of 75? matching coax (Coax R).

The instructions state that tube A can be placed in concrete, but they recommend slightly twisting tube A, while the concrete is setting, for easy removal later.

The manual states "in areas of frequent or heavy winds a set of short non-conductive guys should be used to reduce the stresses that wind loading will impart to the lower sections of the antenna."

As a first estimate, your friends cylindrical radome will have to have a diameter of at least 6", but I'll know more in a few days.

Richard, are you saying to go buy two identical antennas and mount them the same sans coax and then also put another reflector behind the 2nd one, ending up with a 3 element Yagi?
Cliff

"If you want an expected outcome, you do what you have to do and get on

with it. In your case, if you are seeking elegance you would then buy two more units, clamp them base-to-base, put them about a 20th wave behind the first two, and tune the reflector (make it bigger) by that same roughly 5%.

My EE students, noting that the characteristic equations are the same,
regularly convert mechanical problems (of the mass-spring-damper type) into
electrical problems, solve, and then convert back to mechanical answers.
Some ME students catch on and some just do not get it. Of course, it helps
if one is using SI units all round. I continue to be in awe of MEs who
always seem to know whether the "pounds" they are talking of are
sort-of-like mass, or sort-of-like force, or money. I have even had it
suggested that energy and power are sort-of the same thing.

I am keen on Roy being the collector of titles. I have quite enough for
a lifetime. 73 Mac N8TT etc.

Years ago I tracked down a constriction ("resistance") in my house's water system with a bucket and stopwatch to measure flow ("current") and a fuel pump pressure gauge to measure watter pressure ("voltage") and a schematic of the "circuit". I kind of chuckled thinking of all the simplified explanations of electricity using water -- I found it much easier to convert in the other direction.

As for "pounds", I was always off by the acceleration of gravity squared in the only two one-semester courses I took which weren't metric, Statics and Dynamics. I never could remember which of those units -- pounds mass, pounds force, poundals, slugs, aargh, had the acceleration already built in and which didn't. I finally managed by first converting each problem to metric, solving it, then converting the result back to that God-awful system of units.

Has anyone been able to get Eznec to run in Win4Lin (an emulator for running Windows as a Linux application)? I get the startup screen, but then an error window pops up saying EZWf14.DLL is missing. It is in the C:\Program Files/ezw directory (although Windows Explorer does not show it either). It works fine running Windows 98SE natively.

Hi Cliff,

Put them back about ï¿½ wave, and tune them about 3-5% lower in
frequency = Two element yagi. If you want to chip in two more, you
can build them as directors.

I'm sure you're right.

However, a coil/capacitor is not a model or analogue of a
spring/damper system. It was discussed extensively at the time.

Posting under the sock-puppet "Airy R. Bean", he said the following
quoted below, and to which I was referring. I leave it to you to spot
the glaring error. I very much doubt you said anything like this.

The original message was posted in sci.physics at 9:53 am on 21st
January this year.

"Reactance is characterised by the storage of energy.

In the case of the capacitor, you might think that your
AC source is the only voltage source in your circuit, but
after the first 1/4 cycle, the capacitor acts as a voltage source
and starts to give back the energy that it has stored.

The combined result of the two voltage sources, your
AC excitation and the capacitor itself, accounts for
the out-of-phase current waveform.

(This bothered me for years! How could the current
be non-zero if the AC driving voltage was zero?!)

The same analogy applies to springs and to shock absorbers;
the spring stores energy when stretched; the shock-absorber
stores energy when compressed. Both the spring and shock
absorber will return energy at some time and this exhibit reactance!"

Excuse me for 'jumping in' here, it was difficult trying to locate a bit of the thread that referred to the current title (CFA) I would like to ask you learned chaps a question about the 'EH' antenna which I appreciate is not the same as the CFA but its near enough for me:-)

I have built a couple of these and used them on 40m. Performance hasn't been brilliant but they have worked and I was reasonably satisfied with the contacts achieved considering the fact I used a barefoot K2 at around 10 watts o/p and the antenna was sat on the shack bench connected to the K2 by a 1 metre BNC to BNC cable laid across the bench. (I only mention this last to try and forestall the inevitable comment that the feeder does all the work)

All of this was done out of interest just to see if the antenna worked at all, as my gut reaction was, and still is, sceptical regarding the claims of its method of operation. I am not a mathematician, so the various lengthy discussions regarding Maxwell's equations et al pass me by; I am more interested in the practical aspects of this rather than the theory. My question refers to the SWR bandwidth achieved using this system. For an electrically very short antenna of this type I expected something extremely sharp at resonance, perhaps in the order of 5 or 10 KHz between the 2:1 SWR points. In practice, the 2:1 SWR points are some 100 KHz or so apart. When fed with 100 watts from an IC706, the antenna itself does not get warm and neither does the short feeder so it doesn't appear to be acting as a dummy load. Can someone satisfy my curiosity and tell me (drawing comparisons with springs and dampers if need be:-) how this is achieved.

Thanks,
Trev G3ZYY

Sigh.

A couple of questions:

1. Have you tried using something like a loop or other non-magical antenna of similar physical size for comparison? Or putting a 20 dB pad between your rig and a decent antenna? Most people are amazed at how much they can do with 100 mW.
2. I assume you're using a "phasing network" or some similar device to achieve whatever it is the antenna is supposed to accomplish. The wide

bandwidth is a sure sign of loss, and the majority of it is just about surely in the "phasing network" and/or whatever matching network you're using. Have you checked to see if either of them is getting warm after a few minutes of key-down (with breaks to ID of course)?

But don't be surprised it they don't. If you're running 100 watts of CW, your average power output is probably no more than 20 watts while transmitting. If you're running SSB, it's considerably less than that unless you're using serious compression. Try running your rig normally (keying or talking) to a good-sized dummy load and see how long it takes for it to get noticeably warm. Then imagine it to be the size of your matching/"phasing" network and think about what you'd expect to happen if it were absorbing *all* your transmitter's power. It is, after all, absorbing most of it.

Roy,

I think you got as far as my first paragraph and didn't read any
further.

I am not attempting to justify this antenna or the way it works, just
trying to get an explanation for one aspect of it. If you had read what
I had written you would have seen the answer to your questions above.

Is it possible to 'mismatch', for want of a better expression, a loop to
achieve an equivalent bandwidth? I have constructed many short
verticals for portable and mobile use over the years, but have always
experienced narrow bandwidth. It is this aspect of the 'EH' that I
would like to understand.

btw, starting your answer with "Sigh" might be justified if I appeared
to be ignoring your continued advice but surely not at first meeting?

You'll also get that message if DFORRT.dll (which EZWf14.dll needs) is missing, defective, or in a place where EZWf14.dll can't find it, or if EZWf14.dll isn't functioning for any other reason. It also needs MSVCRT.dll, but I don't think Windows will function without that one.

If I were you I'd track down why you're not seeing EZWf14.dll with Windows Explorer. It's a common type of dll, similar to Windows system dlls, and there's no reason it should be hidden.

Trev,
Performance is no better and no worse than what can be expected from any other sort of antenna of about the same physical size and the same length of feedline. Try it and see.

I once worked 3 miles on SSB, on 160m, in broad daylight, with about 10 milliwatts, on 8 feet of wire lying on the ground, thrown out of a downstairs window. The ground connection was via 10 feet of wire from a domestic gas pipe. But I don't brag about it. The credit all goes to Clerk Maxwell.

As Clerk implied, any bloody thing works.

Reg.

Thanks Reg,

I expect you are quite right, but I am still puzzled about the bandwidth aspect. Roy states that this is due to losses in the matching system, in which case would it be possible to 'detune' a similar small antenna and get similar results in that regard. If I can actually do that and see the result, then I will be happy :-)

Try running it it parallel with a suitable resistive load. You will see
increased 'bandwidth', i.e. the SWR will be lower over a greater
frequency range. If you eliminate the aerial altogether then the 'bandwidth'
will cover frequencies up to several GHz with a good quality load ;-)

I have actually worked a local amateur dummy load to dummy load. Both
loads were good quality (one Bird, one Marconi) and all the cabling was
short and good quality coax. Leakage was probably less than a few milliwatts.
The rigs had different IFs so it probably was the signal frequency we were
hearing. Being able to work stations is no measure of antenna efficiency.

Heating is not a good way of determining efficiency unless you do real
calorimetry. I've tried 100W CW key down into a real 100W continuous load
(not one of the Made From Junk ones, which are grossly overrated), for

ten minutes and the temperature increase was just discernible, it certainly didn't get hot.

Yes. Put a resistor in series or parallel with it, or put a pad (attenuator) between it and your rig. When you find the value that gets you the bandwidth of the CFA, you'll also have about the same efficiency. The power will be going into the resistor instead of into the "phasing" and/or matching networks.

I have constructed many short
> verticals for portable and mobile use over the years, but have always

It's loss, plain and simple.

Sort of. You apparently didn't check groups.google.com to see the great mass of postings I and others have made about those antennas, many times before. A tremendous amount has been written and posted about the CFA and EH antennas. But like astrology, homeopathy, and other hoaxes, no amount of objective evidence keeps people from wanting to believe. Either they don't search it out, they're not able to evaluate it when they find it, or they choose to ignore it when it threatens their beliefs. It's resigning myself to that sad certainty and the Sisyphusian (Sisyphusan?) task of combatting it which makes me sigh.

Trev,

As Cecil says, a wider than expected bandwidth in an antenna of given size, is an absolutely sure sign of greater loss somewhere in the wideband antenna system.

Unless one knows how the thing is supposed to work, which with EH and CFA is not very likely, there's no indication of where the loss may be except from a visual examination. If there are any coils of relatively thin wire, either in the antenna or tuner/phaser, then that's a good pointer.

But experimenting to improve the bandwidth*efficiency product, one way or the other, will not get you very far. As one goes up the other is sure to go down. It's not difficult to guess which you would prefer.

A magloop. with a single turn coil of copper pipe at the lower frequencies, is far and away the most narrow banded and therefore the most efficient of all the small antennas. Furthermore it has a built-in, equally very low loss tuner.

Dear Roy:
I am in complete agreement. As an example, when dealing with antenna tower evaluation I convert everything about the tower to SI (knowing the approximate SI density of materials helps to ensure that the conversion was done correctly), and then do the evaluation. When it comes to the design of foundations, I need to convert the SI answer back into the other units so that the skilled trades are able to do their thing.

How silly to have a system that depends on an assumed gravitational system.

Dear John:
Thank you. I understand even more about "A." Is it correct to assume
that the metallic part of "A" is aluminum?

Thank you also for your first estimate of the ID needed to enclose the
whole antenna. That is of great help.

You want QRP, Trev, I'll give you QRP. The telemetry transmitters used on
the early TIROS weather satellites delivered only 10 milliwatts, yet they
produced an S9 signal at a 400 mile high orbit at maximum slant range of
1800 miles to the horizon.

I don't know about other TV satellites, but the RCA Satcoms of the late
70s and early 80s used transmitters that delivered only 5 watts at an
altitude of 23,000 miles. (I will have to admit, however, that 5 watts into
its 30 dB dish produced an EIRP of 5 kw.)

I am not sure I understand your response. To be exact a "spring/damper" can be modeled as a coil/resistor. For resonance to occur you need a capacitor/inductor, or mass/spring. All components of either mechanical or electrical circuits require the solution of the same simple differential equation, such as i = C*dv/dt etc.

I don't know your definition of an "expected bandwidth," but for a reality check--many forms of panel antennas used in FM and TV broadcast transmission have 20% or better SWR bandwidth, and radiate nearly every watt that can be delivered by the feedline with almost NO "matching" losses. They have been in routine use for decades at master antenna transmit sites all over the world.

Thanks for your time Reg,
I drafted a lengthy response to your note above a little earlier but binned it in favour of this :-) I suppose my problem is that I would dearly like to believe the claims for the EH et al but my head tells me that it can't be so. I have had a lot of fun 'playing' with the idea and I suppose I should be happy with that.

I refer you my other post on the subject, where I quote the OP in
full.

>For resonance to occur you need a
>capacitor/inductor, or mass/spring. All components of either mechanical or
>electrical circuits require the solution of the same simple differential
>equation, such as i = C*dv/dt etc.

No-one was arguing that that was not the case. A spring might have the
mechanical equivalent of reactance, but a damper will most certainly
not - hence the rubbish posted by the OP, where he believes that
dampers store energy. They do not, and therefore cannot have the
mechanical equivalence of a reactance. Therefore, resonance is not
possible with such a system. In the extreme, the OP was reduced to
likening dampers to bicycle pumps, a sure sign of a failure to grasp a
fundamental point (and hence the error of his assertion).

Now shrink down those antennas by a factor of, say, 10 in size. Think they'd still do it? If so, you're the natural prey for the charlatans.

In product development, we say fast-cheap-good, pick any two. With antennas it's small-efficient-broadband, pick any two. "Small" is, of course, always in terms of wavelength when it comes to antennas.

==================================

I've no reason to doubt it.

But this is a topic about the bandwidth of physically small HF
antennas.

And as usual, when the slightest difference of opinion occurs,
somebody invariably feels impelled to go off at a tangent and drag in
something they feel more at home with, such as VHF and UHF TV
transmitting antennas, and, very soon, if we are not careful,
distractions such as scattering parameters, reflected power, etc.

While the after picture may represent the condition of your tower after the storm, it is NOT an after picture. Why the false representation?

I am not aware of a damper ever being considered a storage device.
Capacitance is equivalent to mass, Inductance is equivalent to a spring, and
resistance equivalent to a damper. Am I missing something?

Anyway will read later posts and see what I can get out of it.

Is this what you are talking about?

"The same analogy applies to springs and to shock absorbers;
the spring stores energy when stretched; the shock-absorber
stores energy when compressed. Both the spring and shock
absorber will return energy at some time and this exhibit reactance!"

I think we have been at cross purposes. The above is nonsense.

Bob,
The storm was not a pinpoint single line width across the map but over 3 0 0 m i l e s wide. I did not measure the "winds in Union". If they were not high enough for you then maybe better luck next time.

According to the storm category indications on the map at

http://www.wunderground.com/tropical/tracking/at200504.html

"Hurricane Dennis" was actually a "tropical depression" before it ever
crossed into Mississippi, some distance north of Union.

Charlie, I would never wish high winds upon anyone, but before you
brag about riding out a Category 4 Hurricane, you should be a little
more accurate in your terminology :-)

Have a good one...

Thank you, Owen, for kicking aside the roadblocks preventing me from understanding your math presentation. I get it now, and realize I was a knothead for being confused.

It is now perfectly clear why one can't get the true answer using my expressions for calculating loss on the line when using only the nominal Zo and not the actual Zo when there is loss. I should have known that intuitively, and why it escaped me is puzzling.

Studying your math approach let me see the light, and for that I thank you. And thank you also for taking the time to teach me.

Walt

PS--I note from your telephone numbers in your email to me that you are not located in the US. Also, the name Duffy sounds somewhat British. Are you in the UK?

Charlie, you may have noticed that the thread died once people realised you are out of town and not endangering anyone else. Good on you for putting up a tower out there, what the hell, eh? But the distortions aren't exactly helpful.

More to the point, how's the DX'ing? I used to have to go to a nearby mountainside road to get any height like you have now.

Cheers.

Ken

Nope. But the OP, now posting as 'Polymath', had said "The same analogy applies to springs and to shock absorbers; the spring stores energy when stretched; the shock-absorber stores energy when compressed. Both the spring and shock absorber will return energy at some time and this exhibit reactance!"

But the shock-absorber stores...nothing, and can return nothing. It therefore cannot have the mechanical equivalent of reactance, and cannot therefore be a part of a frequency-determining mechanism. He had failed to appreciate the property of mass - a rather fundamental point. That is why I said he was an idiot - a claim I see no reason to change.

Yep, those tropical depressions can be rough -- let us know next time
it rains in Union -- we'll want to see "before & after" pics of your
tower.

There are no distortions Ken. The tower looks the same the day before Dennis as it does now the day after. The WHOLE POINT in using 2 identical photos was to illustrate that there IS NO DIFFERENCE after the storm.

I have been on Usenet for 20 years or more and it is always the same....people just wait in the wings to take pot shots at others. I posted a link to the tower photos and all I got was ridicule and cuss words.

Now that it survived the affects of hurricane Dennis I get accusations that Dennis never even came near my home.
You guys can all go fish..or any other "F" word you might be able to think of.

Sorry to rob you all of the splendor of viewing my new tower down on the ground.

You fuckers are all a bunch of real sick bastards.

Charlie, the assessment that the "tower looks the same the day before
Dennis as it does now the day after" is your own assessment, then to
convince others, you misrepresent a "before" photograph as an "after"
photograph as evidence to support your assessment.

The photograph is not honest, it portrays what is in your mind rather
than what is on the ground, and IMHO is only evidence of what is in
your mind.

Might have been a nice point if you did take an after photograph.

As to the extent that you experienced Hurricane Dennis, I will leave
that to you guys to work out.

Owen

Just posting a real 'after' shot would have shut people up (well, most, as you say).

Anyway, still glad it didn't come down. My only beef was ever the neighbours - since they aren't in sight (and I notice you don't seem to have your house near it either) I say go for it.

Cheers.

Ken

Hi Bob,

I've been running Win4Lin for years, since the original alpha pre-1
days, and never had anything, well anything normal, that didn't work,
including RadioMobile. And Roy's program seems to be pretty normal in
how it talks to the OS.

Which version of Win4Lin? The new one that does XP?

Did the install look clean? No hiccups during it?

If there was anything at all suspicious, get in touch with Win4Lin
support, they are quite good at following up.

Just because the antenna wasn't damaged in this storm doesn't mean it
its installation is safe. So it withstood a storm whose biggest claim
to fame around her is flood damage.

Will the antenna stand the test of time?

Good luck

This group has vast experience, so I was wondering what any of you have worked on, or just plain know about, the so called T-wave range of frequencies. Which would be roughly 100GHz to 10THz.

And if you have worked on it, what can you tell us about it? It seems to have some interesting potential, similar to XRay in some ways, but also sensitive to chemical properties.

While I'm not going to "plonk" you, I would advise you to get better guy anchors. Trees and utility poles aren't up to the task. If it was me, I'd set some 6 or 8 inch steel pipe about four to six feet into a BIG block of cement leaving six or seven feet out of the ground. Have lugs welded to the pipe and attach the guys to the lugs. This will get the guys up over head high and allow grass cutting and the like around the posts. When the tree comes down, so will your tower. Of course, using two different brands of tower section was just foolish, the money spent on making a possibly faulty adapter could have gone for another good section of tower. But, hey, it's your tower and your money. As for me and mine, good engineering practice takes precedence over make-do every time. Another amazing fact is that someone climbed up there to put it up and set antennas. It must have been a crazy man, as no sane tower-monkey would have climbed up there on two different tower sections and faulty guying. Be sure and post photos of the wreck when it comes down,eh.

I tried the demo (successfuly) and am pretty sure the problem is that I can't find my original EZW version 3 to version 4+ upgrade file and copying the c:\Program Files\EZW directory from my Win 98SE partition (which I want to delete eventually) either didn't give me all the files I needed or the registry won't recognize something. I'll try installing version 3 (I still have the CD for that), which is less capable, but better than the demo.

And they say something like "not to be used for identification" right on
the cards. The way things are going, we will probably all need to carry
passports before long.

Yeah. They say all sorts of things over here too.

Internal passports... nice Tsarist idea, kept up by the KGB.

This must be boring people who haven't killfiled us all who are looking for
a discussion on aerials or electrical engineering (don't worry about being
off topic on uk.radio.amateur - *we* all are) so I'd best QRT on this here
breaker channel.

I encourage people having any problem with EZNEC to email me. But I think this is of general interest to all users of Windows programs as well as EZNEC, so I'll continue posting here for a short while. It is drifting away from anything to do with antennas, though, so it should be taken to email if it's not resolved very soon.

Like many Windows programs, EZNEC requires files and Registry entries which which are installed with the installation program but not in the EZNEC program directory. So it won't function properly or at all if you just copy the program directory from another computer or operating system. (The demo program is a little more tolerant this way and you might get away with it, depending on what you already have installed on your machine. But don't count on it.) The only way to produce a functioning full-version program is to install it on the target system using the installation program. This also holds true for many other Windows programs. Sorry, Toto, we're not in DOS any more.

Anyone who purchases an upgrade doesn't get an "upgrade file". You get the complete newer version of the program which doesn't require the old version to install or run. An upgrade just gets you a special price, not a different program.

Email me if you need to make arrangements to download the program again.

For those of you who have EZNEC or might purchase it in the future -- if you aren't able or willing to back up the downloaded file, spend the extra $10 for the CD. I heartily recommend this for all programs, not just EZNEC.

My antenna and ground mount came to me a used equipment/
The mounting post that came along is fantastically designed. Let me
try to describe it to you:
Galvanized steel water pipe four feet in lenght with a nominal Inner
diameter of about 1 inch.
One end has a taper point (very much like a sand point well point)
wellded to it..

The opposite end (side that vertical and atenna insulater is dropped
into) has 3 in by 3 inch " ears welded parrallel to the length of the
pipe, 5 inches from the end and 180 aprt from each other.
The welded steel ears are about 3/16 of an in thick. Each ear has a
3/8 inch hole drilled through them about 3/4 of an inch from the top
of the ear. This permits hooking 1/4 or 5/16 proof coil chain as a
point to remove pole using a convienent fulcrum or jack.
I use a 10 pound mall to drive the pole into medium hard ground. I
strike the ears, not the pole. When you get to ground level with the
ears continue to drive the ears to the bolt holes. This pole will
never rotate.

It is almost easier to fabricate this than it is to describe it.
Completely removable and reusable mount.
Two 3/16 holes are drilled through the fiberglass insulator and
through the mount where I have number 10 -24 stainless hardware.

Ron

Message-ID: <06HAe.59657$ho.10121@bignews6.bellsouth.net>
Source record: 73433

Hi

I have a 260 OCF dipole that I wouldl like to hang but the largest span between trees is about 220 ft. at about 60 ft high on one end and 80 ft on the other.

1. How will the antenna performance be affected if I let the ends just drop staright down?

2. The long side is 166 ft, short side 94 ft. - if letting the ends drop down is OK, would it make a difference to put the vertical amount on one side. If so, would it be best to let the extra drop vertically on the long side? short side? or best to even up the extra on both ends?

Thanks in advance.

What do you guys think of the Gap Antennas - they have the Titan, etc.

I like the designs of the butternuts better in general...

How many of you have had experience with
elevated radials?

I'm one....

Four elevated radials at the correct length and
height are supposed perform as well as many ground mounted radials.

Yes, at the correct height above the ground in terms of *wavelength*.
I would not expect super results with 4 radials, below about 1/4 wave
above the ground. And that 1/4 wave above ground will be a different
height for each band. A 1/2 wave up would be better, but may be
impractical on the low bands. I used 4 radials on a 40m ground plane,
at 36 ft at the base. Just a bit over a 1/4 wave up. Worked quite well,
and
was equal to appx 60 radials on the ground. But drop down to 1/8 wave,
and you will need *many* more than 4 radials for the same amount
of ground loss. At 1/2 wave up, 4 radials are appx equal to 100-120
on the ground. Real low "IE: 5-10 ft high" elevated radials are just
barely
better than having them on the ground on the lower bands. Even
20 ft up, will be pretty lackluster, unless you have a lot of them, or
are using a
high frequency. 20 ft is higher than a 1/2 wave on 10m. ..
I found 1/4 wave up to be the lowest height for really *good* results
when
using only 4 radials. Any lower, and it drops to *mediocre*
performance...

Thanks for the answer - good empirical information about elevated radials.
I forget, though: how *long* do the elevated radials have to be in terms
of wavelength? For example: what would you recommend for a 1/4 wave
high 80m vertical?

Idea: If you are not using it on 160m, make it 130 ft instead
of 260 ft.

> 1. How will the antenna performance be affected if I let the ends just drop
> staright down?

You won't notice much difference on the lower bands. Since the
drooping ends will be an appreciable percentage of a wavelength
on the higher bands, you may notice some additional directivity.

You reckon Eugene Hecht was lying when he shows us how to
add two irradiances to obtain the total irradiance (power
per unit-area) in _Optics_? Adding EM wave powers during
interference is a well accepted way of handling EM wave
superposition in the field of optics. The bright constructive
interference rings contain more power than the dark destructive
interference rings. RF waves and light waves are both electro-
magnetic waves, just at different frequencies. Asserting that
RF waves obey a different set of laws of physics than do light
waves is naive ignorance at best.

2679. zip cord feeding a g5rv antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-12 20:44:33 UTC
From: pegge <pegge.j@DELETEtelia.com>
Message-ID: <RYVAe.29028$d5.182116@newsb.telia.net>
Source record: 73445

someone tried to feed a type g5rv antenna with ?european? zip-cord ?
(european meaning double the Volts compared to USA, thus half amps
for the same lamp wattage)
Would yield a simple ant, peel the first say abt 15- 17 meters, splitting
them up to the dipole part and the the rest X meter to a balanced tuner etc.
sorry if this has been up too many times, search did?nt give a clue!

Tnx for info, 73 Per / sm7aha malmo, sweden

Hi Per,

Hard to apply the name g5rv to this, but that makes no difference
anyway. Simply call it a dipole driven with close spaced twin lead.
That twin lead will be 50 to 70 Ohms characteristic impedance. It
will also have a suspect dielectric loss. This does not make it a bad
antenna. There will be the usual high loss with high SWR - depending
upon the gauge of the wire.

In short, no worse than an ordinary antenna used outside of its
natural resonance.

Source record: 73448

The radials need to be resonant if they are elevated. IE: 1/4 , 3/4
wave,
etc... For 80m, they will need to be appx 60-65 ft long. MK

Eugene Hecht doesn't have a dog in this fight, Cecil. But the quote is a truism that applies in any case. Wrong numbers added correctly produce a wrong number; correct numbers added incorrectly produce an incorrect number; and in the special case, certain wrong numbers added in a particular incorrect way can produce a desired result.

You take too great a liberty with the name Eugene Hecht. Among the things which won't be found in any of Dr. Hecht's texts is a minus sign in front of number expressing an irradiance. Nor will we find a negative scalar quantity accompanied by the claim that the negative sign indicates a change in direction, as you have done. Eugene Hecht also did not claim that interference could be a cause for energy to reflect or otherwise change direction, as you have done. Such claims are blatently false.

Power and irradiance are derived and dependent quantities, not fundamental independent quantities in nature. And although an automobile moves at some speed, the scaler quantity itself is not something which moves. Similarly, power and irradiance do not physically propagate and they do not physically interact. 'They' do not reflect, refract, diffract, disperse, interfere, or act upon other 'powers' or 'irradiances'. JC Maxwell and others observed that it is electric and magnetic fields which propagate, interact with matter, and add algebraically and vectorially. When fields physically interact with matter, we can measure their effect and can quantify such things as voltage, current, and heat, and hence calculate such things as power or irradiance. But it is actually the fields themselves which algebraically sum. Of course the interference equation accurately

expresses power and irradiance. The fact that power and irradiance generally go as the square of the fields allows us to correctly make certain additional mathematical assumptions. One must still be careful not to mistake an effect for a cause. But it is the 2nd Amendment, the internet, and the absence of peer review which afford men the freedom and means to work equations and describe physical phenomena in any way they like.

A commercial version of this antenna (6m moxon) is available. I put one up last year and am VERY pleased with it. You can find it in the AES catalog (Amateur Electronic Supply). I forget who offers it, but it is something like 79 bucks, if you have neither the time nor the inclination to build one.

> You take too great a liberty with the name Eugene Hecht. Among the
> things which won't be found in any of Dr. Hecht's texts is a minus sign
> in front of number expressing an irradiance.

Sure wish you would read the book before making such statements.

On the contrary, here's equation (9.16) representing total destructive
interference.

Imin = I1 + I2 - 2*SQRT(I1*I2) = 0

The third term is indeed a minus sign in front of a number expressing
irradiance. However, total average irradiance cannot be less than zero.
And for the record, I have never said total average power could be less
than zero but, like Hecht, I treat destructive interference energy as a
negative term and constructive interference energy as a positive term.

Dr. Stephen Best, VE9SRB, did the same thing for his "Wave Mechanics
of Transmission Lines, Part 3:" QEX article, Nov/Dec 2001. He said:

"When the voltages V1 and V2 are exactly 180 deg out of phase, the
total power can be determined as follows:"

"PFtotal = P1 + P2 - 2*SQRT(P1)*SQRT(P2)"

so if you don't like negative power terms, you should confront both
Eugene Hecht and Dr. Best.

> Nor will we find a
> negative scalar quantity accompanied by the claim that the negative sign
> indicates a change in direction, as you have done.

On the contrary, in equation 9.16 above, according to Hecht, the
interference term is negative indicating "total destructive
interference", his words, not mine. Here's Hecht's quote from _Optics_.

ï¿½The principle of
conservation of energy makes it clear that if there is constructive
interference at one point, the ï¿½extraï¿½ energy at that location must have
come from somewhere else. There must therefore be destructive
interference somewhere else."

Sorry, but a negative interference term denotes destructive
interference. A positive interference term denotes constructive
interference. In a transmission line with only two directions,
if destructive interference occurs in one direction, then
constructive interference must occur in the only other direction
in order to satisfy the conservation of energy principle.

A wave cancellation event in a transmission line implies an equal
constructive interference event in the opposite direction. Anything
else violates the laws of physics.

> Similarly, power and irradiance do not
> physically propagate and they do not physically interact.

On the contrary, they do physically interact for coherent waves as can
be inferred by the interference equations. Please reference Chapter 9
in _Optics_, by Hecht. The mathematical interaction of power and
irradiance is a *result* of superposition of coherent EM waves. That's
where the interference equations involving irradiance come from.

> JC Maxwell and others observed that it is
> electric and magnetic fields which propagate, interact with matter, and
> add algebraically and vectorially.

And contain power equal to ExH. EM waves cannot exist without energy.
If EM waves interact, their energy components interact. Destructive
and constructive interference cannot occur without energy components
which follow the laws of physics.

> Of course the interference equation accurately expresses power and
> irradiance.

That is some progress on your part so there's hope. What you need to
realize is that those interference equations define what happens to
the energy at a match point in a transmission line. Dr. Best kicked
this discussion off by his QEX article. He just didn't realize that
the equations he published were virtually identical to the classical
optical interference equations.

NOT FOR DISASTER RELIEF FUNDS but Federal assistance for Debris Removal and Emergency services ... NOT A DISASTER AREA. Nice Exaggeration!

Additionally, Brown said the state and affected local governments in 23 counties are eligible to apply for federal funds to pay 100 percent of the approved costs for debris removal and emergency services related to the hurricane, including requested emergency work undertaken by the federal government, for a period of up to 72 hours.

The 23 counties designated eligible for the assistance include Clarke, Covington, Forrest, George, Greene, Hancock, Harrison, Jackson, Jefferson Davis, Jones, Kemper, Lamar, Lauderdale, Lowndes, Marion, Neshoba, Newton, Noxubee, Pearl River, Perry, Smith, Stone, and Walthall.

Well, this will be my last post on this thread. I think Charlie has burnt his last shred of credibility by using identical images for "before" and "after" evidence. I'm sure everyone noted that not even a single tree leaf was lost during that disaster, so I suppose Charlie could also claim that his tower is as strong as a leaf, maybe even stronger!

Since Charlie doesn't seem to worry too much about factual evidence, his request for technical comments must have been posted for entertainment value, and in that, he certainly has succeeded. Can we look forward to annual updates posting the same original image, thereby proving that Chuckie has not only built a strong, but an eternal tower?

Richard Clark wrote:
> [Hecht rolls his eyes]

I'm going to trim and ignore the condescending ad hominem stuff.

> ... the math follows the physics, it does not create the physics.

Your argument has that exact flaw. "What Cecil is describing doesn't exist in the common math model. Therefore, the math model prohibits it from existing in physics." Please follow your own advice. There is a vast gulf between being descriptive and being prohibitive.

> There is a vast gulf between being descriptive and being proscriptive.

I didn't choose to quote the entire book, Richard. Hecht also says: "If two or more electromagnetic waves arrive at point P out-of-phase and cancel, 'What does that mean as far as their energy is concerned?' Energy can be distributed, but it doesnï¿½t cancel out. ... The superposition of coherent waves generally has the effect of altering the spatial distribution of the energy but not the total amount (of energy) present."

"Altering the spatial distribution of the energy" in a transmission line is a binary function since there are only two directions. If the spatial distribution is altered, it necessarily changes directions.

The following does explicitly state a change in direction, i.e. "A NEW DIRECTION".

http://micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index.html

"When two waves of equal amplitude and wavelength that are 180-degrees out of phase with each other meet, they are not actually annihilated. All of the photon energy present in these waves must somehow be recovered or REDISTRIBUTED IN A NEW DIRECTION, according to the law of energy conservation ... Instead, upon meeting, the photons are redistributed to regions that permit constructive interference, so the effect should be considered as a redistribution of light waves and photon energy rather than the spontaneous construction or destruction of light." (Emphasis mine.)

A transmission line has only two directions. If wave cancellation, i.e. permanent destructive interference, takes place in one direction, the necessary corresponding constructive interference must be "redistributed in a new direction". In a transmission line, there is only one "new direction", the opposite direction from the old direction.

Hang tough & enjoy your tower Charlie!
If it breaks, fix it. Otherwise enjoy it!

Some day I may get brave and post the pictures of my fold over-crank
up mast with the CushCraft A3 beam on it. It waves around in the wind
like a sailboat mast and flexes the I-beam gantry enough to scare the
clueless when it is time to do antenna work.

When mine breaks, I will either fix or replace, just as I have always
done...

My current worries are lightning and ice.

It has only been up about five years, time will tell.

I have a 40meter band xmit/recv antenna up with good swr and works great.
Cost me nothing but my time, and a plastic center insulator to strain
releive the zip cord (rather than tie a knot in the cord at the center. Just
rip down 33 ft of zip cord, tie a knot or use the insulator, and cut the
feedlinne section to a integral half wave long (20, 40, 60etc meters long).
If cut to a half wave (use a dip meter) the swr of the dipole will be
translated unaltered to the radio end of your feedline and 70 ohms is OK for
a swr of 1.4 and the xcvr will not care usually.

Great emergency antenna.

2700. Re: Really low SWRs but is it worth trimming the antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-13 17:00:54 UTC
From: tjs <anon@anon.net>
Message-ID: <42d54ccf_2@news1.prserv.net>
Source record: 73379

Your SWRs are great (as the antenna is setup now) dont bother fixing them. A good antenna, maybe with some gain, usually only has a bandwidth of the 40 channels. The SWR will be maybe 2:1 at ch1 then go low to 1:1.4 at ch20 then back to 2:1 at ch 40..will work just fine. Actually your SWRs sound too good to me, for antennas with loading coils.

If you change the antenna the SWR WILL change so you will need to tune it up. You want more gain, in some direction, right? well you're going to loose gain in all the other directions. Focusing the signals by setting up the antenna like in a beam makes the antennas SWR curve narrower, 2:1range may only go from ch10 to ch 30. And the SWR will go up, so you need the gamma match you see on the driven elements to fix the problem.

Apparently Peneterators are 12 ft long, with a load in the center (a lousy compromise). There would be a matching coil at the base probably too whether theyre 1/2 wave or 5/8th antennas. A real 5/8th antenna will be 21 ft high with no loading coils, dont skimp on heighth .

If they are 5/8th antennas and you have mounted these base to base then you have made an Extended Double Zepp which has gain of maybe 4-6db (2.5-4X signal gain) and can focus the signals on the horizon (I assume these are mounted vertically not horizontally out from the sides of a tower). you would need to put the base to base mount at least 40ft off the ground, one pointing up/one down.

Adding a director or reflector will not do much for you, since you already have pretty good antenna (assuming its working right!) A Zepp antenna (end to end 5/8th antennas, 42 ft long) is a great vertical if high enough and it puts you power on the horizon.

You have to make allowances for Mrs.Nugatory. As always,
I responded very quickly to a genuine request for help, but
responded to the lead given by the questioner who
mentioned spring/damper rather than spring/mass, and so
I responded off-the-cuff without too much forethought.

Better a quick response than none at all, or a response that
had the hallmarks of a 13-year old mind that requires a
literal meaning for everything, as does Mrs.Nugatory!

I acknowledged the error in a subsequent posting but Mrs. Nugatory
is a chronic paranoid obsessive who latches onto every thing that I say,
and hounds the thing to death, as she is doing below, many months
after the ephemeral chit-chat has ceased to have any relevance.

For example, if you seek out the time that I alerted Usenet users to
the availability of cheap dehumidifiers, Mrs.Nugatory managed to spin out
over 50 pages of insistence that I knew nothing about them!

Mentally deranged, or what!

Don't be foolish. Obviously neither of the P terms can be negative if PFtotal is supposed to represent a real number. I have no issues to confront with either of the gentlemen. It is where you diverge from Hecht (and Maxwell, and Born and Wolfe, and Jackson) that I take issue.

>> Nor will we find a negative scalar quantity accompanied by the claim

> interference", his words, not mine. Here's Hecht's quote from _Optics_.

One statement does not contradict the other, as the subject in each sentence is entirely different. Both statements are obviously true.

>> Similarly, power and irradiance do not physically propagate and they
>> do not physically interact.
>

> where the interference equations involving irradiance come from.

As I explained they come from the fact that the fields interact, and that power and intensity (or irradiance) go as the square of the field. Lets say the square of F1 (field 1) is proportional with P1, and the square of F2 is proportional with P2. And lets say the mathematical description of the way the two fields interact is as follows: Ftotal = (F1 - F2)*(F1 - F2). (Looks kinda like modulation, but I digress.) We can then write that as Ftotal = F1^2 + F2^2 - 2*F1*F2. By substitution then, PFtotal = P1 + P2 - 2*SQRT(P1*P2). And that's where your favorite equation comes from.

Message-ID: <1121286116.913758.137580@g43g2000cwa.googlegroups.com>
Source record: 73465

Hi, all --

Looking for guidance: I want to do some virtual experimenting with small transmitting loops before I start welding up a few of the real things. Questions:

* Is NEC, or one of its children, good for this sort of work?

* Do I need NEC/4, or will NEC/2 do?

* Can models handle curved conductors? If I have to enter a zillion straight segments, OK, but I'd rather not.

* Will the model handle lumped impedances, e.g. the matching capacitor at the far side of the loop?

* Does NEC take Q issues (conductor resistance, capacitor leakage) into account?

* Can I usefully model over ground (ideal and real)? I have read claims that STLs aren't affected by height-above-terrain, and I rather suspect that it simply hasn't been convenient to hang the contraptions half a lambda in the air, and the writers are just whistling past the antenna range.

...I guess that's about enough topics to start a thread. Thanks.

What a con job.
100 years ago, today: $4.87
40 years ago, today: $2.80
30 years ago, today: $2.20
20 years ago, today: $1.39
10 years ago, today: $1.60

Robust must mean slumped by 63% - One Time Constant?

Any boost of some 11% in the past decade certainly has to be
attributable to the White House running the printing presses full
steam.

You seem to have a reading comprehension problem, Fred. Nowhere did I
say that "the actions of the government are responsible" for anything I
do. I simply gave an example of the rampant hypocrisy and the false
morals of the so-called social conservatives whose actions somehow don't
match their alleged morality and perceived social and moral superiority.
Anything else you're reading into this is your own construct.
The reason I cited that example is because it is almost identical to
your rants against my "profanity", "gutter language" and "foul mouth".
For some strange reason you social conservatives are unable to grasp the
simple concept of *not* reading/watching/viewing/listening to whatever
offends you. Is that so difficult?

2719. Feed point chokes for J-poles: how close?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-13 21:18:33 UTC
From: Ben Jackson <ben@ben.com>
Message-ID: <slrnddb199.kj.ben@saturn.home.ben.com>
Source record: 73473

In a multi-band J-pole (where higher frequency j-poles are basically
mounted on the long leg of the next lower frequency leg) can the feedpoint
chokes for all the bands be located at the base of the antenna, or do they
need to be kept right by the J's for each band? The "copper cactus" has
the feeds running up the center pole and poking out holes in the tube
for each feedpoint. That would require putting the chokes at the base of
the mounting stub.

Yep, providing that if there's more than one turn, the spacing between turns is at least a wire diameter or two.

> * Do I need NEC/4, or will NEC/2 do?

NEC-4 will handle somewhat smaller loops, but double precision or mixed precision NEC-2 will probably be adequate. NEC-2 is free; NEC-4 is several hundred dollars.

> * Can models handle curved conductors? If I have to enter a
> zillion straight segments, OK, but I'd rather not.

Conductors must be straight, but NEC-2 has the provision for automatically generating segments in a circle if you can figure out how to do it. EZNEC (my program) fully automates the process.

> * Will the model handle lumped impedances, e.g. the matching
> capacitor at the far side of the loop?

Yes.

> * Does NEC take Q issues (conductor resistance, capacitor
> leakage) into account?

Only to the extent that you know them and therefore can tell the program how large the loss resistance or conductance is.

> * Can I usefully model over ground (ideal and real)? I have read
> claims that STLs aren't affected by height-above-terrain, and I
> rather suspect that it simply hasn't been convenient to hang the
> contraptions half a lambda in the air, and the writers are just
> whistling past the antenna range.

Yes.

I recommend that you download the free EZNEC demo program from http://eznec.com. It's adequate to do the modeling you describe, provided that the loop has only one or two turns. There's no time limit or restriction on its use. And it includes the full EZNEC manual.

>>Why do you think the SWR of the dipole will be unaltered at the radio end
of the feedline? You are apparently >>ignoring the loss in the line that
makes the SWR at the radio end less than that at the dipole terminals.

>>If the zip cord had zero loss the SWR would be the same everywhere along
the line, only the terminal impedance at >>the radio end would be the same
as at the dipole.

>>Without knowing the vf (velocity factor) of the zip cord how do you
determine that the length is a half wave?

>>And last, why would you want the length to be a half wave?

>>Walt, W2DU

I think he was correct about the half-wave length of feedline:
according to the ARRL Antenna Book - 17th edition copyright 1994 - page
24-12 in chapter 24, under the Heading "Special Cases" and under the
sub-heading "The Half-WaveLength Line", it pretty clearly states that
regardless of z, it will be the same on both ends of a half-wave line. and
sections having such length can be added or removed without changing the
load Z. (as long as loss is negligible)

Also - You don't need to know the VF if you use a dip meter (or MFJ 259) -
And he would want the length to be half-wave so as to be able to ignore the
characteristic impedence of the zip line and deal directly with the
impedence of the dipole directly.

Hmmm,

The British Empire must, as one would expect, have an Emperor, and
particularly a British Emperor. If we scan the list of Royals over
time, certainly Britain had an Emperor (Carausius) during the Roman
era (hardly worth claiming as being British when you bend your knee to
Rome and that empire didn't even claim Wales).

Nearly as far back ago, there was a ship called Emperor.

There are a specie of penguins called Emperor.

Almost 100 years ago there was a George who went by Emperor and like
our own was numbered. But it wasn't George Trois, in fact it was
suggested that this George adopt the title "Emperor of the British and
Hanoverian Dominions," but he refused (and this suggestion only came
after 1802).

If we rummage around the list of Monarchs, then we find our recent
George, and Edward before him were "Emperors" and only of India. The
first "Emperor" was in fact an Empress (of that same named India).

So, by the question above, it must be discerned that in fact no one
ever took up arms against a GREAT BRITISH EMPIRE nor a MODEST BRITISH
EMPIRE nor even a PIDDLIN' BRITISH EMPIRE. So this usage of BRITISH
EMPIRE must in some sense mean the East India Trading Company (since
the only monarchs called Emperor/Empress are uniquely associated with
that sole state in our antipodes. The East India Trading Company held
property in Hudson Bay, so to put this presumed conflict into the
desired NON-POLITICAL way
Canadian (the people, not the political country) Consumers
revolting against a commercial entity - eh? What a bunch of hosers.

Anyone who underestimates the toughness, tenacity, and resilience of the
British people is a fool. The Irish Republican Army waged a terrorist
campaign against London for years without having any effect
whatsoever on British resolve. While I'm no fan of the British,
I'd like to see some of our whining, sweat-drenched, paranoid
patriots make a stab at doing even half as well.

Hi Tom,

Funny about that. Before the election, the cost of Gas taxes pushing
a gallon over $2 would cripple us. Instead we pay $2.50 and the
economy is just fine thank you and the arabs get more than the tax
revenue we didn't add. Let's see, we pay them more, take in less tax,
and add a 10 year off-budget item of $100 Billion. Sounds like
Osama's slush fund is doing better than the market. Could be the
golden investment for social security diversion if you didn't end up
in a Git'mo rest home for the aged financial supporters of terrorism.
Who knows? Filling up your gas tank could get you to the tropics
sooner than you might imagine. Flown there on 'Merican Oil? (Such
irony anticipated in the goofs there too.)

A trillion here, and a trillion there, and soon you are talking about
real money.... Let's see, if a million monkeys printed a million
dollars a decade, how much would a banana cost by the next election?

There's one chimp that doesn't care.

Sorry, OM, as I told Richard in the above post, this hasn't been one of my better days. I read that you used the MFJ 259 to measure the length, but it just didn't register until Hall pushed it into my face. Tnx, Hal. I promise not to get out of bed tomorrow. How much harm can I do there? Don't answer that question.

I don't diverge from them, Jim. I have simply tied a few loose
ends together using logical deduction based on the laws of physics.
So far, you have produced zero instances where I diverge from
the laws of physics. OTOH, you appear to have diverged quite often,
e.g. Maxwell's equations prove that standing waves can exist without
a rearward-traveling wave, cancelled waves don't contain energy or
momentum before they are cancelled, reflected waves are not re-
reflected by wave cancellation, there is no before and after, etc.

> PFtotal = P1 + P2 - 2*SQRT(P1*P2). And that's where your favorite
> equation comes from.

I have said all along that energy cannot be separated from the waves
containing the energy and that's why an energy analysis is possible.

Yes, Richard described that process pretty accurately I thought.

> So far, you have produced zero instances where I diverge from
> the laws of physics.

I produced three just yesterday.

> OTOH, you appear to have diverged quite often,

Please provide exact quotes. Otherwise, you're taking liberties with
the truth.

> I have said all along that energy cannot be separated from the waves
> containing the energy and that's why an energy analysis is possible.

Yes you have said that, whatever it means. Born and Wolf has an
interesting comment in the section on total reflection. "...the
electromagnetic field in the second medium does not disappear, only
there is no longer a flow of energy across the boundary."

2735. 20m 5el Yagi Question: Gain vs Height

Newsgroup: rec.radio.amateur.antenna
Date: 2005-07-14 02:40:17 UTC
From: Ken Bessler <kg0wx@NOSPAMyahoo.com>
Message-ID: <kgkBe.8782$Eo.6158@fed1read04>
Source record: 73401

I was modeling a 5el 20m yagi. I changed antenna
height over realistic ground. As I expected, lowering
from 50' to 25' changed the take off angle from 18
degrees to 28 degrees.

What suprised me was the forward gain went from
14.44 dbi (@50') to 12.63 dbi (@25').

Is this normal?

Most of your past objections are personal opinions that
have been based on a lack of understanding of what I was
saying. Please list just one law of physics from which
I have diverged. I do not think you can do that.

On second thought -
If you feed it like that, then it will cease to be a G5RV.

Your interest in that frequency range indicates you may have researched it at least a little. Why don't you go first, and tell us about it. The sensitivity to chemicals sounds like an interesting place to begin.

> Is this normal?

Yes. A quick run of EZNEC with example file 20m5elYa shows just about the same difference. Notice that the main lobe is much fatter when the antenna is lower -- that's what happened to the gain. Everything else being equal, a fatter lobe means less gain, since you have only so much power to spread around.

I also ran a 3D plot so I could see the Average Gain. With no other sources of loss, it indicates how much is lost in the ground reflection. The lower antenna loses about 0.4 dB more than the higher one. That accounts for 0.4 dB of the loss -- all the rest is because of the change in pattern shape.

As a further educational exercise, try modeling a dipole at those two heights and see what the gain difference is.

Roy Lewallen, W7EL

Hi OM,

Directional anomalies, as you put it, with asymmetric counterpoises
are academic at best. For FM, you would have to be well below levels
of full quieting before you noticed it (the partial dB anomaly); or in
your case of SSB (vertical?), by definition (and certainly practice)
you couldn't possibly hear less than the dB shift (for one, you would
have no basis of comparison as you would have no way of shifting it
in/out to discover the anomaly).

And on the third hand, the academic anomaly in all likelihood is in a
direction that is wholly outside of your normal propagation usage.

This can be cobbled up with the free version of EZNEC to confirm or
negate.

>impedence of the dipole directly.

This analysis seems to imply use of the antenna on only one one band.

Ill conceived alternative feed arrangments are the most common reason
why so-called G5RVs performs even poorer than the "genuine" article.

The original question about how well "Euro zip line" will perform will
depend on the characteristics of the line. I hazard a guess that it
will be unlikely to have a characteristic impedance as low as 75 ohms
as suggested by some, more likely 100 ohms or more. It is likely to be
PVC insulated, and lines of that type perform much poorer than a high
z line made of the same conductor, not just because of the dielectric
issue, but because the RF resistance of the conductor increases as the
spacing is reduced for very close spacings (proximity effect).

As to whether it "works" for you, you need to define your criteria for
"works". If "works" means you make some QSOs, then I am sure it
"works", but if "works" meand you want to deliver 80% plus of the
transmitter power to the "G5RV variant" antenna feedpoint on several
bands, then it is unlikely to "work".

For arguments sake, if the feedpoint Z of a 30.5m centre fed dipole
(G5RV length) on 3.6MHz is 10-j340, using the characteristics of US
Zip cord measured by K8ZOA, the loss in 25m of such feeder would be
13dB with a Zin of 563-61, so there would be some small
(insignificant) additional tuner loss. Is this what you mean by
"works"?

Owen

sure, closer to the ground you get more loss in the ground. also there may be some power going into other lobes and also the vertical lobe may be wider giving lower peak gain. this is one of the big reasons to do modeling, the changes in pattern and gain do not always follow what you might expect.

I would like to be able to determine if antenna is present at the end of a piece of coax. In some case antennas of type ?? would have a DC resistance across the coax and that makes it easy. But..., how would you easily determine if a coax shows an infinite DC resistance (NO RETURN PATH) no current flow - like simple did-poke.
